Global, regional, and national trends in routine childhood vaccination coverage from 1980 to 2023 with forecasts to 2030: a systematic analysis for the Global Burden of Disease Study 2023

*GBD 2023 Vaccine Coverage Collaborators**

Summary

Background Since its inception in 1974, the Essential Programme on Immunization (EPI) has achieved remarkable success, averting the deaths of an estimated 154 million children worldwide through routine childhood vaccination. However, more recent decades have seen persistent coverage inequities and stagnating progress, which have been further amplified by the COVID-19 pandemic. In 2019, WHO set ambitious goals for improving vaccine coverage globally through the Immunization Agenda 2030 (IA2030). Now halfway through the decade, understanding past and recent coverage trends can help inform and reorient strategies for approaching these aims in the next 5 years.

Methods Based on the Global Burden of Diseases, Injuries, and Risk Factors Study 2023, this study provides updated global, regional, and national estimates of routine childhood vaccine coverage from 1980 to 2023 for 204 countries and territories for 11 vaccine-dose combinations recommended by WHO for all children globally. Employing advanced modelling techniques, this analysis accounts for data biases and heterogeneity and integrates new methodologies to model vaccine scale-up and COVID-19 pandemic-related disruptions. To contextualise historic coverage trends and gains still needed to achieve the IA2030 coverage targets, we supplement these results with several secondary analyses: (1) we assess the effect of the COVID-19 pandemic on vaccine coverage; (2) we forecast coverage of select life-course vaccines up to 2030; and (3) we analyse progress needed to reduce the number of zero-dose children by half between 2023 and 2030.

Findings Overall, global coverage for the original EPI vaccines against diphtheria, tetanus, and pertussis (first dose [DTP1] and third dose [DTP3]), measles (MCV1), polio (Pol3), and tuberculosis (BCG) nearly doubled from 1980 to 2023. However, this long-term trend masks recent challenges. Coverage gains slowed between 2010 and 2019 in many countries and territories, including declines in 21 of 36 high-income countries and territories for at least one of these vaccine doses (excluding BCG, which has been removed from routine immunisation schedules in some countries and territories). The COVID-19 pandemic exacerbated these challenges, with global rates for these vaccines declining sharply since 2020, and still not returning to pre-COVID-19 pandemic levels as of 2023. Coverage for newer vaccines developed and introduced in more recent years, such as immunisations against pneumococcal disease (PCV3) and rotavirus (complete series; RotaC) and a second dose of the measles vaccine (MCV2), saw continued increases globally during the COVID-19 pandemic due to ongoing introductions and scale-ups, but at slower rates than expected in the absence of the pandemic. Forecasts to 2030 for DTP3, PCV3, and MCV2 suggest that only DTP3 would reach the IA2030 target of 90% global coverage, and only under an optimistic scenario. The number of zero-dose children, proxied as children younger than 1 year who do not receive DTP1, decreased by 74·9% (95% uncertainty interval 72·1–77·3) globally between 1980 and 2019, with most of those declines reached during the 1980s and the 2000s. After 2019, counts of zero-dose children rose to a COVID 19-era peak of 18·6 million (17·6–20·0) in 2021. Most zero-dose children remain concentrated in conflict-affected regions and those with various constraints on resources available to put towards vaccination services, particularly sub-Saharan Africa. As of 2023, more than 50% of the 15·7 million (14·6–17·0) global zero-dose children resided in just eight countries (Nigeria, India, Democratic Republic of the Congo, Ethiopia, Somalia, Sudan, Indonesia, and Brazil), emphasising persistent inequities.

Interpretation Our estimates of current vaccine coverage and forecasts to 2030 suggest that achieving IA2030 targets, such as halving zero-dose children compared with 2019 levels and reaching 90% global coverage for life-course vaccines DTP3, PCV3, and MCV2, will require accelerated progress. Substantial increases in coverage are necessary in many countries and territories, with those in sub-Saharan Africa and south Asia facing the greatest challenges. Recent declines will need to be reversed to restore previous coverage levels in Latin America and the Caribbean, especially for DTP1, DTP3, and Pol3. These findings underscore the crucial need for targeted, equitable immunisation strategies. Strengthening primary health-care systems, addressing vaccine misinformation and hesitancy, and adapting to local contexts are essential to advancing coverage. COVID-19 pandemic recovery efforts, such as WHO's Big Catch-Up, as well as efforts to bolster routine services must prioritise reaching marginalised populations and target subnational geographies to regain lost ground and achieve global immunisation goals.

Introduction

Building on the success of the global campaign to eradicate smallpox, the Expanded Programme on Immunization (EPI) was launched in 1974 by WHO to extend the benefits of universal immunisation against common childhood diseases worldwide.[1] EPI initially supported the deployment of vaccines to combat diphtheria, tetanus, pertussis, polio, measles, and tuberculosis. Over the ensuing 50 years, EPI—now renamed the Essential Programme on Immunization—has added more childhood vaccinations, recommending vaccinations for all children globally against hepatitis B, *Haemophilus influenzae* type b, pneumococcus, rotavirus, and rubella, along with a second dose of the measles vaccine, while broadening to include recommendations for adolescent vaccination against human papillomavirus.[2] Through partnerships between local health-care workers, national immunisation programmes, regional authorities, and international organisations, EPI has achieved remarkable health gains. The effect of making routine childhood immunisation (ie, regular and ongoing immunisation services, often delivered during routine health visits) widely available has been drastic, resulting in an estimated 154 million deaths averted globally between 1974 and 2024, with nearly 95% of those in children younger than 5 years.[3]

For more on the **Vaccine Confidence Project** see https://www.vaccineconfidence.org/

Although delivering routine childhood vaccinations worldwide requires a tremendous investment of global resources, including approximately US$3·9 billion in development assistance for health in 2023,[4] childhood immunisation has proven to be one of the most successful and cost-effective public health strategies known, both in terms of lives saved and return on investment.[5,6] Estimates have shown the financial rate of return to be in some instances up to 44-times the cost of vaccination.[7] Yet the remarkable successes of EPI have slowed in the past decade and in some cases reversed, suggesting weaknesses in health services that were further exposed during the global upheaval caused by the COVID-19 pandemic, including social distancing measures, health system diversions, and supply chain disruptions. Previous estimates suggest that coverage with the third dose of the diphtheria, tetanus, and pertussis vaccine (DTP3) decreased in 94 countries and territories between 2010 and 2019, and only 11 countries worldwide were estimated to have reached the 2019 target set by the WHO Global Vaccine Action Plan of at least 90% coverage for all assessed vaccines.[8] As coverage has stalled, new and increased outbreaks of vaccine-preventable illness, such as measles, polio, and diphtheria, have emerged in many countries and territories.[9]

To successfully further the reach, equity, and sustainability of global immunisation systems, it is necessary to overcome enduring and emerging challenges, such as growing economic uncertainty and geopolitical instability that constrain funding for vaccination and global health, migration, and population displacement,[10,11] geographical and sociodemographic disparities in access to vaccines,[12–17] disruptions to immunisation delivery related to events such as natural disasters or widespread infectious disease outbreaks such as those caused by the SARS-CoV-2 and Ebola viruses,[18–22] and an upsurge in vaccine misinformation and hesitancy as detailed by the Vaccine Confidence Project.[23,24] To meet these challenges, WHO's World Health Assembly endorsed Immunization Agenda 2030 (IA2030),[10] an updated framework to envision and achieve universal immunisation, building on the previous Global Vaccine Action Plan approach with a broader scope and increased tailoring for local contexts.[25] Focused on centring the expertise of local and country-level partners and authorities,[26] aligned with the UN's Sustainable Development Goal 3 to ensure healthy lives and promote wellbeing for all at all ages,[27] IA2030 sets an ambitious global agenda to achieve "a world where everyone, everywhere, at every age, fully benefits from vaccines to improve health and well-being".[28] One of IA2030's primary goals is to promote equity by halving (relative to 2019) the number of zero-dose children, that is, children missed by routine childhood vaccination, typically proxied by estimating those who have not received any DTP doses. Zero-dose children are more likely to miss out on subsequent vaccinations[29] and experience other types of deprivation,[17] and strategies to reach these missed children with vaccination services can bolster routine health services more broadly. IA2030 further emphasises the necessity of extending the benefits of vaccination throughout the life course, reaching beyond early childhood to deliver essential catch-up vaccinations and booster doses, along with a growing number of new vaccines scheduled for administration after childhood. To this end, IA2030 sets a goal of achieving 90% global coverage for vaccines across the life course, including DTP3, the third dose of a pneumococcal conjugate vaccine (PCV3), the second dose of a measles-containing vaccine (MCV2), and the complete human papillomavirus vaccine series (HPVc).[10,28] These ambitious targets are important to prevent the resurgence of vaccine-preventable diseases and to foster strong and resilient immunisation and health-care systems that will serve as a platform for the introduction of new vaccines. The need for strong

Research in context

Evidence before this study

Accurate and comprehensive estimates of childhood immunisation coverage are essential to guide efforts to combat vaccine-preventable disease and to measure progress in the global campaign launched 50 years ago by EPI—the Expanded Programme on Immunization—to provide all children, everywhere, access to life-saving vaccines. Annual WHO–UNICEF Estimates of National Immunization Coverage (WUENIC), reliant on expert local knowledge and qualitative reasoning to compile and evaluate country-reported administrative and household survey data, have served as an important source of information on routine childhood vaccine coverage since 2000. Previous work from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) further applied comprehensive statistical models to systematically analyse these disparate survey and country-reported coverage data sources in an overarching framework designed to address recurrent issues of data sparsity (ie, incomplete data from some countries and regions), heterogeneity (ie, variability in sampling frameworks), and bias (ie, systematic errors in data collection) and to formally quantify estimation uncertainty in vaccine coverage from 1980 to 2019. Both WUENIC and GBD estimates showed marked global increases in coverage across vaccines since 1980, but slower progress and in some settings declines in coverage from 2010 to 2019. Subsequently, following the onset of the COVID-19 pandemic in 2020, numerous sources—including WHO global pulse surveys on continuity of essential health services, country-reported administrative data, WUENIC estimates, and GBD models—suggested large disruptions to vaccination services. Early GBD statistical models of monthly administrative data estimated large and heterogeneous disruptions to vaccination coverage during 2020, with variable recovery as the year progressed, leading to millions of children missing vaccine doses in that year. The Scorecard for the Immunization Agenda 2030 (IA2030), the comprehensive global vision and strategy to reduce death and illness from vaccine-preventable disease, shows that as of 2023, global vaccine coverage levels had still not returned to pre-COVID-19 pandemic levels, and progress towards coverage targets for 2030 is not on track. Still missing, however, is a comprehensive, statistical, quantitative assessment of the long-term effects of the COVID-19 pandemic on childhood routine immunisation and its effect on progress towards the IA2030 targets.

Added value of this study

Building on the established GBD evidentiary and analytic framework, the present study refines these models and extends this time series by leveraging additional years of data and improved analytic techniques to generate updated and extended estimates of annual routine childhood vaccination coverage in 204 countries and territories from 1980 to 2023 for 11 childhood vaccine-dose combinations—targeting diphtheria, tetanus, and pertussis (first and third doses [DTP1 and DTP3]), measles (MCV1 and MCV2), polio (any three doses of the polio vaccine [Pol3]), tuberculosis (BCG), hepatitis B (HepB3), *Haemophilus influenzae* type b (Hib3), *Streptococcus pneumoniae* (PCV3), rubella (RCV1), and rotavirus (RotaC; complete series). We complement these estimates of historic coverage trends with three secondary analyses designed to contextualise recent disruptions in coverage due to COVID-19 and progress needed between now and 2030 to achieve important targets set by IA2030. In these analyses, we (1) assessed the effect of the COVID-19 pandemic on routine childhood immunisation from 2020 to 2023 by comparing declines in coverage attributable to the COVID-19 pandemic with coverage levels expected in the absence of the pandemic, (2) rigorously evaluated progress needed to reach the IA2030 goal of a 50% reduction in numbers of zero-dose children (proxied as children younger than 1 year who have never received a dose of DTP1), and (3) forecasted the plausibility of reaching IA2030's 90% global coverage targets for life-course vaccines by generating forecasts of DTP3, PCV3, and MCV2 coverage for 2030—the last representing the first forecasts published for PCV3 and MCV2 coverage.

Implications of all the available evidence

The overarching public health benefits of the first 50 years of EPI have been immense, saving the lives of an estimated 154 million children and providing a total of 10·2 billion years of full health. This was achieved through a near doubling of global rates of immunisation against diphtheria, tetanus, pertussis, measles, polio, and tuberculosis between 1980 and 2023, a reduction in numbers of unvaccinated zero-dose children by more than 70%, and the introductions of a multitude of crucial new vaccines and vaccine-dose combinations (including HepB3, Hib3, MCV2, PCV3, RotaC, and RCV1). However, substantial disparities persist, including markedly lower coverage and higher rates of under-vaccinated and unvaccinated children in the low-income and middle-income countries, especially sub-Saharan Africa, with over 52·6% (95% uncertainty interval 51·4–53·8) of zero-dose children living in sub-Saharan Africa and 12·5% (11·4–14·8) living in south Asia. Moreover, stagnating immunisation progress worldwide after 2010, COVID-19 pandemic-related decreases in coverage for all five original EPI vaccine-dose combinations (BCG, DTP1, DTP3, MCV1, and Pol3), and increases in the number of zero-dose children that have persisted into 2023 make it unlikely that ambitious IA2030 goals will be reached unless considerable course correction occurs. Enduring and emerging socioeconomic inequities related to rising numbers of displaced people and growing disparities due to armed conflict, political volatility, economic uncertainty, climate-related crises, and vaccine misinformation and hesitancy stand as fundamental obstacles to extending equitable vaccine coverage. Advancing equitable childhood vaccination will require both collective global engagement and the input of local stakeholders to shape vaccination strategies responsive to context-specific realities and to build confidence in immunisation policies. It will require the political and financial will to ensure robust primary health-care systems that can support the strong, resilient, equitable immunisation programmes needed to continue delivering existing vaccines, to serve as a platform to provide new vaccines as they become available, and to expand their reach and promise to all.

routine health systems to enable vaccine delivery was underscored during the pandemic and holds true today as new vaccines for malaria, dengue, Ebola virus, and other diseases are being developed and deployed.

To advance universal childhood immunisation, a core principle of IA2030 is reliance on high-quality, targeted data to guide immunisation policies and programmes and to better measure progress extending vaccination coverage. Since 2000, a key source of vaccination data has been the WHO–UNICEF Estimates of National Immunization Coverage (WUENIC),[30] which uses a rules-based approach to provide annual routine vaccination coverage estimates for all WHO member states using expert judgement and qualitative knowledge to compile primary data from available sources. WUENIC estimates use country-reported and administrative data gathered through the WHO–UNICEF Joint Reporting Form (JRF)[30–32] and are informed by data from established household surveys, such as the Demographic and Health Surveys (DHS) Program and the Multiple Indicator Cluster Surveys. These estimates from WUENIC incorporate expert judgement and qualitative knowledge in their comprehensive compilation of primary data sources; however, the rules-based approach might lead to flat or noisy time trends, particularly in data-sparse locations, and is not able to account for uncertainty in the estimation process.[32] Previous work from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) has applied a comprehensive statistical model to these data to systematically generate national estimates of vaccine coverage from 1980 to 2019.[8] Because primary vaccination data can be inconsistent (ie, discrepant sampling methods and/or results),[33] sparse (ie, few data in specific locations), and subject to bias (ie, systematic error imposed through biased sampling methodology),[34,35] the use of a statistical model to derive coverage estimates confers multiple advantages. These include the capacity to synthesise data from heterogeneous sources while accounting for the effects of discrepant data quality and types (eg, administrative *vs* survey) as well as the presence of systematic bias; to overcome data sparsity by leveraging time trends and other predictors; and to formally quantify estimation uncertainty.

See **Online** for appendix 1

Here, following the 50th anniversary year of EPI's founding and halfway through the decade of IA2030, we build on the framework of the previous GBD vaccine coverage study[8] to generate updated estimates of vaccine coverage for 204 countries and territories from 1980 to 2023. We analyse progress over time in the coverage of key childhood vaccine-dose combinations and estimate trends in numbers of zero-dose individuals. We extend the previous GBD analysis to include the COVID-19 era, including many data sources delayed in reporting by the COVID-19 pandemic. We deploy new methods to account for the immediate and enduring effects of the COVID-19 pandemic in a unified framework, enhance estimation of the scale-up of newly introduced vaccines, and improve our estimation of counts of zero-dose children by modelling the first dose of the diphtheria, tetanus, and pertussis vaccine (DTP1) directly. Looking forward, we assess progress towards the IA2030 goals of 50% reduction in zero-dose children and 90% global coverage of select life-course vaccines in secondary analyses. First, building off an early framework developed by Causey and colleagues,[18] we use a counterfactual approach to quantify the effect of the COVID-19 pandemic on the number of children who missed routine vaccinations between 2020 and 2023. Second, we evaluate progress needed to reach a 50% reduction in zero-dose children by 2030. Last, we forecast future DTP3, PCV3, and MCV2 coverage up to 2030 under three scenarios to show the range of plausible future trajectories. These comprehensive, updated estimates show progress and challenges in the effort to immunise against routine childhood diseases, providing crucial evidence to inform policies, programmes, and investments aimed at ensuring that all children, everywhere, receive life-saving vaccinations.

This manuscript was produced as part of the GBD Collaborator Network and in accordance with the GBD Protocol.[36] Because newly available data and modified methods were used to update the full time series of estimates from 1980 to 2023, these results supersede all previous estimates.

Methods

Overview

To generate coverage estimates of routine childhood vaccination in 204 countries and territories from 1980 to 2023, our core analysis followed the previous GBD methods,[8] applying a multistep modelling approach using spatiotemporal Gaussian process regression (ST-GPR)[37] and meta-regression—Bayesian, regularised, trimmed (MR-BRT)[38] tools to synthesise data collected primarily through the WHO–UNICEF JRF[31] and through household surveys (appendix 1 pp 242–43). Annual country-specific coverage estimates were calculated for 11 childhood vaccine-dose combinations supported by EPI and administered via routine national immunisation programmes, including five vaccine-dose combinations from the four vaccines introduced in 1974 against diphtheria, tetanus, and pertussis (DTP1 and DTP3), measles (first dose of a measles-containing vaccine [MCV1]), polio (third dose of any form of polio vaccination [Pol3]), and tuberculosis (BCG)—plus six vaccine-dose combinations rolled out in subsequent years (newer vaccines) targeting hepatitis B (third dose [HepB3]), *Haemophilus influenzae* type b (third dose [Hib3]), rotavirus (complete series; RotaC), pneumococcus (PCV3), rubella (first dose of a rubella-containing vaccine [RCV1]), and measles (MCV2). Our core model adjusted for location-varying and time-varying bias in

country-reported data from the JRF; leveraged data-dense evidence for specific locations, years, and vaccines to estimate coverage in instances of data sparsity; accounted for vaccine disruptions and country-specific years of vaccine introduction; and propagated uncertainty. Details regarding our innovations to the previous GBD methods and novel secondary analyses are provided in the sections below.

This study complies with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) statement (appendix 1 p 14).[39] Analyses were done with R version 4.4.0. Statistical code used for estimation is publicly available on the Global Health Data Exchange.[40] Additional methods details are available in appendix 1 (pp 2–6).

Data

We reviewed 8042 data sources between 1980 and 2023, of which 1085 unique sources were included in the analysis (representing 128 new sources compared with the previous GBD vaccine coverage study,[8] including 37 new sources from 2020 to 2023 and 91 from 2019 and earlier). These sources comprise 64 546 country-year-vaccine-dose-specific datapoints, including 14 700 datapoints from vaccination-related household surveys (eg, DHS, Multiple Indicator Cluster Surveys, and other multicountry and country-specific surveys), 49 800 datapoints from administrative and official country-reported vaccine coverage data from the JRF and other sources, and supplemental data regarding stockout events, vaccine introductions to national immunisation programmes, and vaccine schedules, also reported through the JRF.[41–44] Data were catalogued and are publicly available on the Global Health Data Exchange.[40] As in the previous study,[8] we grouped coverage data by birth cohort (12–23 months, 24–35 months, 36–47 months, 48–59 months—excluding cohorts younger than 1 year at the time of the survey) and—to align survey-based data with country-reported data—used county-specific vaccine schedules and vaccine introduction years to assign each cohort to the year of expected vaccine delivery. For the complete inclusion and exclusion criteria see appendix 1 (pp 2, 15–216, 244).

Modelling of administrative data bias

To account for bias in country-reported coverage data,[45] as in the GBD 2020 study, we used the MR-BRT modelling framework to assess differences in coverage within paired observations of survey data and original country-reported coverage from the same country-years. This bias was modelled as the ratio of survey data coverage to country-reported coverage, adjusting for the Healthcare Access and Quality (HAQ) Index (a composite index designed to assess and compare health-care access and quality),[46] with the expectation that bias in reporting might vary based on the quality of health-care services. These MR-BRT bias predictions then served as a first-stage input for ST-GPR models. These bias adjustments were only applied directly for the original EPI vaccines; estimates for newer vaccines leveraged bias adjustments for the original EPI comparator vaccines through the ratio modelling process. New for this study, bias was directly modelled for both DTP1 and DTP3, rather than DTP3 only (appendix 1 p 3).

Modelling of stockouts and other disruptions to vaccine coverage, including COVID-19

To account for acute temporal disruptions (ie, drops) in coverage due to stockouts or other isolated events, we first modelled the magnitude of disruptions for vaccine-country-years with reported stockout events reported via the JRF[42] or other identified disruption events (appendix 1 pp 217–227). Disruption magnitudes were then included as a covariate in vaccine coverage modelling. New in this study, this covariate was devised by calculating the difference in coverage between country-reported data in vaccine-country-years identified as experiencing disruptions and counterfactual coverage estimates from models that excluded these vaccine-country-years. To account for disruptions due to COVID-19, also new to this study, we considered all vaccine-country-years for 2020 to 2023 as candidates for disruption events (appendix 1 p 3). New in this study, for vaccine-country-years in this period without available country-reported data, we imputed disruption magnitudes based on vaccine-year-specific distributions from locations with data (appendix 1 p 4).

For more on **R** see https://www.R-project.org/

Vaccine coverage model

Our core analysis relied on modelling in ST-GPR to implement a multistep approach that produced location-specific annual estimates of vaccine coverage for 11 routine childhood vaccine-dose combinations in 204 countries and territories over the period of 1980 to 2023. ST-GPR is a stochastic modelling tool designed to synthesise heterogeneous inputs and flexibly smooth data over space and time, leveraging available high-density data to guide predictions in cases of absent or sparse data and to minimise prediction error.[37] The model uses a three-stage approach, starting first with a regression incorporating covariates that might affect vaccine coverage. The second stage implements spatiotemporal smoothing, and the final stage uses a Gaussian Process regression to reduce error around high-precision data.

Improvements to this study include modifications to the modelling strategy for DTP. In previous GBD cycles, DTP3 coverage was modelled directly, and DTP1 was estimated with a continuation ratio ordinal regression approach.[8] For GBD 2023, with increasing global focus on zero-dose children (proxied as those who have not received DTP1), we now model DTP1 directly and, to ensure internal consistency where DTP1 must be greater than DTP3, estimate DTP3 by modelling the DTP3/DTP1 ratio.

For more on **Armed Conflict Location and Event Data** see https://acleddata.com/

For **Uppsala Conflict Data Program** see https://ucdp.uu.se/

For **Ethiopia's Tigray War** data see https://www.ethiopiatigraywar.com

For the directly modelled vaccines—DTP1, MCV1, Pol3, and BCG—country-specific and year-specific estimates of coverage were produced using ST-GPR models fit to bias-adjusted official country-reported data and survey data. ST-GPR models included covariates for the HAQ Index;[46] mortality rates due directly to war and terror events as per data from Armed Conflict Location and Event Data, Uppsala Conflict Data Program, and Ethiopia's Tigray War data; and vaccine disruptions. We also used this approach to model the ratio of DTP3/DTP1 coverage (using bias-adjusted official country-reported data and survey for both numerator and denominator), which was multiplied post-hoc by our modelled estimates of DTP1 coverage by draw to calculate DTP3 coverage.

For other vaccines, we modelled the ratio of coverage to that of one of the original EPI vaccines, using ST-GPR to allow for similarities and differences in these relationships across space and time. DTP3 served as the denominator, or reference vaccine, for modelling HepB3, Hib3, PCV3, and RotaC vaccine coverage ratios, given that it is typically given either as part of a combination vaccine and/or on the same schedule as these vaccines, whereas MCV1 was used as the reference vaccine for MCV2 and RCV1, to ensure that MCV2 coverage does not exceed MCV1 coverage, and because RCV1 is often delivered in a combination vaccine with MCV1. All ratios were constrained to be less than one, assuming newer vaccine coverage will be less than the original corresponding reference vaccine. New for GBD 2023, we estimated the scale-up of each newer vaccine ratio as a function of years since introduction. By explicitly modelling scale-up patterns and allowing these to vary by country and vaccine, we improved estimation in early years after introduction and in settings with sparse data. We fit predictive spline models of coverage ratios using MR-BRT in a geographical cascade: vaccine-specific models were first fit across all countries and territories, and the global model fits then served as priors for country-specific models. In this process, coverage ratios were modelled as a function of vaccine disruptions, years-since-introduction (fit using a spline), and a country-level random effect (appendix 1 pp 4, 245). The results of these spline models were used as first-stage estimates in subsequent ST-GPR coverage ratio models. Last, we multiplied the predicted coverage ratios from ST-GPR by the corresponding reference vaccine coverage to generate final estimates of coverage.

Uncertainty was propagated by sampling 1000 random draws from the posterior distribution of each modelling step and conducting all subsequent calculations by draw. Results were summarised using the mean of all draws and the ordinal 2·5th and 97·5th percentile of draws to compute 95% uncertainty intervals (UIs). Super-regional and global aggregate estimates were calculated at the draw level as target population-weighted means (appendix 1 p 228).[47,48] In-sample and out-of-sample goodness of fit statistics were calculated (appendix 1 p 5). Coverage estimates were also compared with estimates from the previous GBD 2020 vaccine coverage study and estimates published by WUENIC in 2024 (appendix 1 pp 7–8).[8,49]

Secondary and post-hoc analyses

To understand the effect of the COVID-19 pandemic on childhood vaccination rates, we calculated vaccine coverage in a counterfactual (ie, alternative) scenario in which coverage was not affected by disruptions due to COVID-19 (COVID-free). This was done by removing post-hoc the disruption covariate effects from coverage estimates in 2020–23 (appendix 1 p 5). To account for potential disruptions that would have occurred even without the COVID-19 pandemic, we applied an adjustment scalar to the counterfactual estimates based on country-draw-level averages of disruption sizes for the preceding 5 years (2015–19; appendix 1 p 246). This year range was chosen to reflect the most recent patterns in the occurrence and magnitude of disruptions.

To assess progress towards the IA2030 goal of reducing the number of zero-dose children globally by half by 2030, compared with 2019, we considered a hypothetical scenario where all countries and territories reduce zero-dose children by 50% between these years (ie, equal contributions towards this goal). Using GBD population forecasts,[50] we calculated the number of zero-dose children needed to be reached by 2030 and corresponding DTP1 coverage. To contextualise required DTP1 coverage increases, we calculated the 2023–30 annualised rate of change (AROC) in DTP1 coverage needed for each country to meet this target (appendix 1 p 6). We then compared these to the distribution of AROCs across historical 7-year periods from 2000 to 2019 for all countries and territories.

To predict progress towards IA2030's target of 90% coverage in 2030 for routine childhood vaccination across the life course, we adapted methods of Foreman and colleagues[51] and GBD 2021 Forecasting Collaborators[52] to forecast future coverage for DTP3, PCV3, and MCV2. We produced reference vaccine coverage forecasts for 2030 that capture the most likely reference future scenario. Forecasted DTP3 coverage for the reference scenario was estimated in a predictive modelling framework that leverages historic relationships between vaccine coverage estimates and the Socio-demographic Index (SDI), a composite indicator measuring a country's development status, with a logistic regression framework with SDI as the sole covariate.[48] To show a plausible range of future coverage trajectories, we also produced alternative better and worse scenario forecasts based on historic rates of change. The better and worse scenario estimates were forecasts based on the 85th and 15th percentiles, respectively, of the distribution of past rates of change in coverage (in natural log space) between subsequent years. The historic distributions were calculated by draw, pulling from across countries and territories and all year pairs between 1980 and 2019, excluding years affected by the

COVID-19 pandemic. Rates of change from more recent years were weighted more heavily in the distribution compared with those from earlier in the time series. Forecasts of PCV3/DTP3 and MCV2/MCV1 coverage ratios were produced using equivalent ratio modelling techniques as used in historical coverage estimation. We then multiplied by forecasted DTP3 and MCV1 estimates, respectively, for each scenario to calculate PCV3 and MCV2 coverage (appendix 1 p 6).

Results

Trends in vaccine coverage, 1980–2019

Between 1980 and 2019, global vaccine coverage for the original EPI vaccines—BCG, MCV1, DTP1, DTP3, and

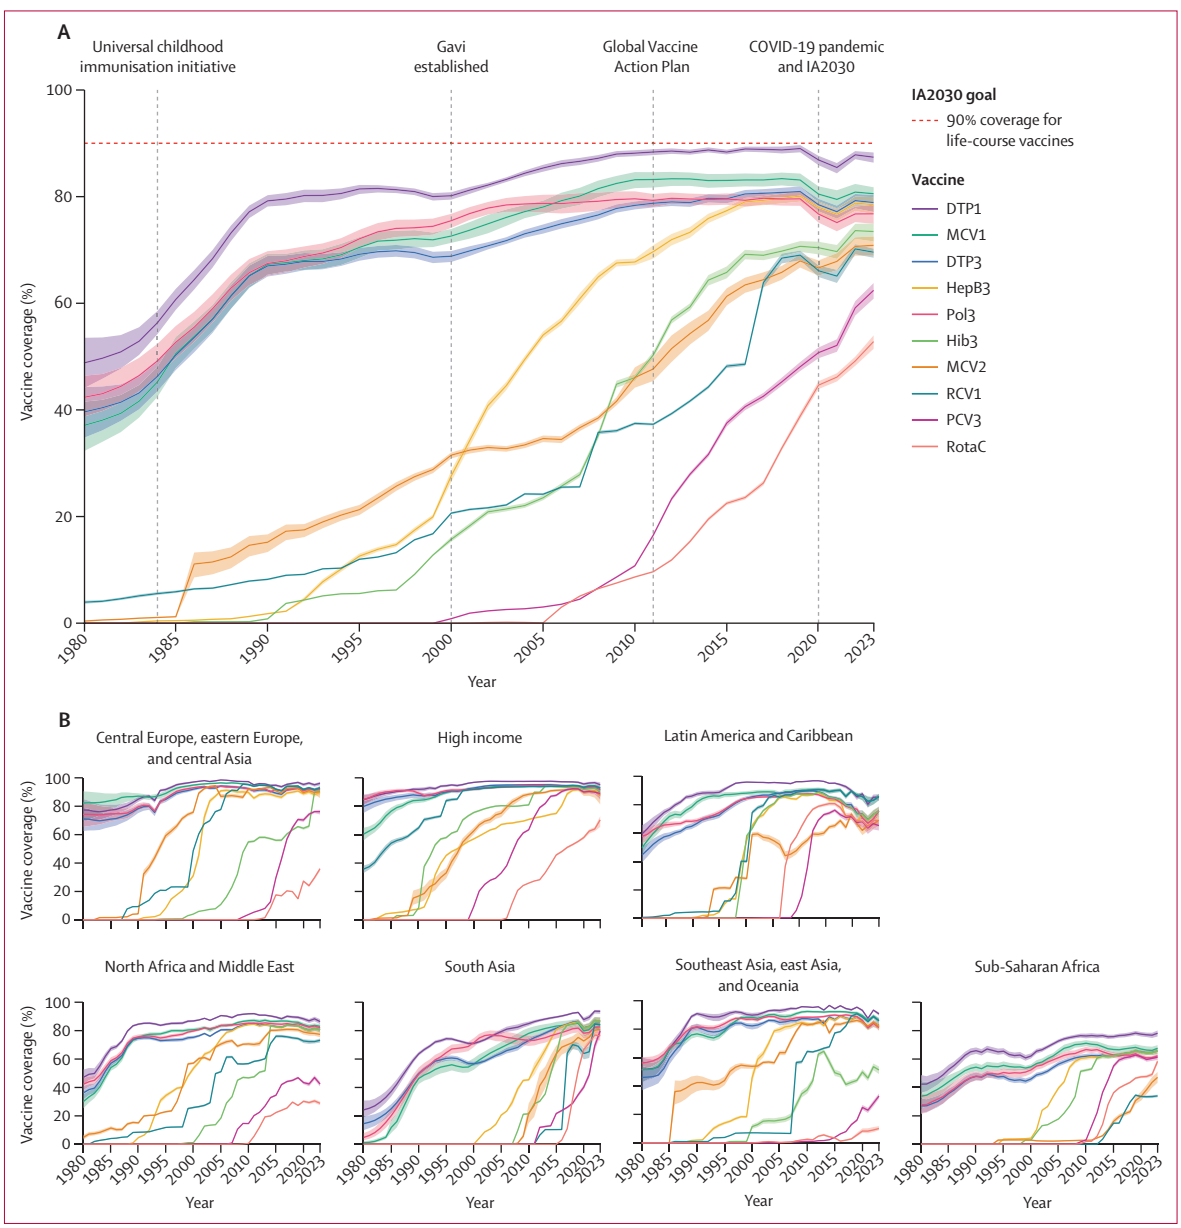

Figure 1: **Global and super-regional estimates of vaccine coverage over time**

Mean global (A) and super-regional (B) coverage estimates for the target age population by year for each vaccine, with 95% uncertainty intervals. The dashed horizontal line indicates the coverage required to meet the IA2030 goal of 90% coverage for life-course vaccines. DTP1=diphtheria-tetanus-pertussis, first dose. DTP3=diphtheria-tetanus-pertussis, third dose. Gavi=Gavi, the Vaccine Alliance. HepB3=hepatitis B vaccine, third dose. Hib3=Haemophilus influenzae type b vaccine, third dose. IA2030=Immunization Agenda 2030. MCV1=measles-containing vaccine, first dose. MCV2=measles-containing vaccine, second dose. PCV3=pneumococcal conjugate vaccine, third dose. Pol3=polio vaccine, third dose. RCV1=rubella-containing vaccine, first dose. RotaC=completed rotavirus series.

Pol3—approximately doubled, from 38·1% (95% UI 33·9–42·3) in 1980 to 83·3% (82·7–84·0) in 2019 for BCG, 37·1% (32·3–41·6) to 83·1% (81·8–84·3) for MCV1, 48·8% (44·1–53·5) to 89·0% (88·3–89·6) for DTP1, 39·6% (34·8–44·3) to 80·9% (79·9–81·9) for DTP3, and 42·4% (38·8–46·4) to 79·6% (78·3–81·0) for Pol3 (figure 1; appendix 1 pp 247–485). Across this timeframe, this equates to an estimated 4·1 billion (4·07–4·12) children vaccinated with BCG, 4·01 billion (3·98–4·04) with MCV1, 4·48 billion (4·45–4·51) with DTP1, 3·89 billion (3·85–3·93) with DTP3, and 4·00 billion (3·96–4·04) with Pol3 through routine

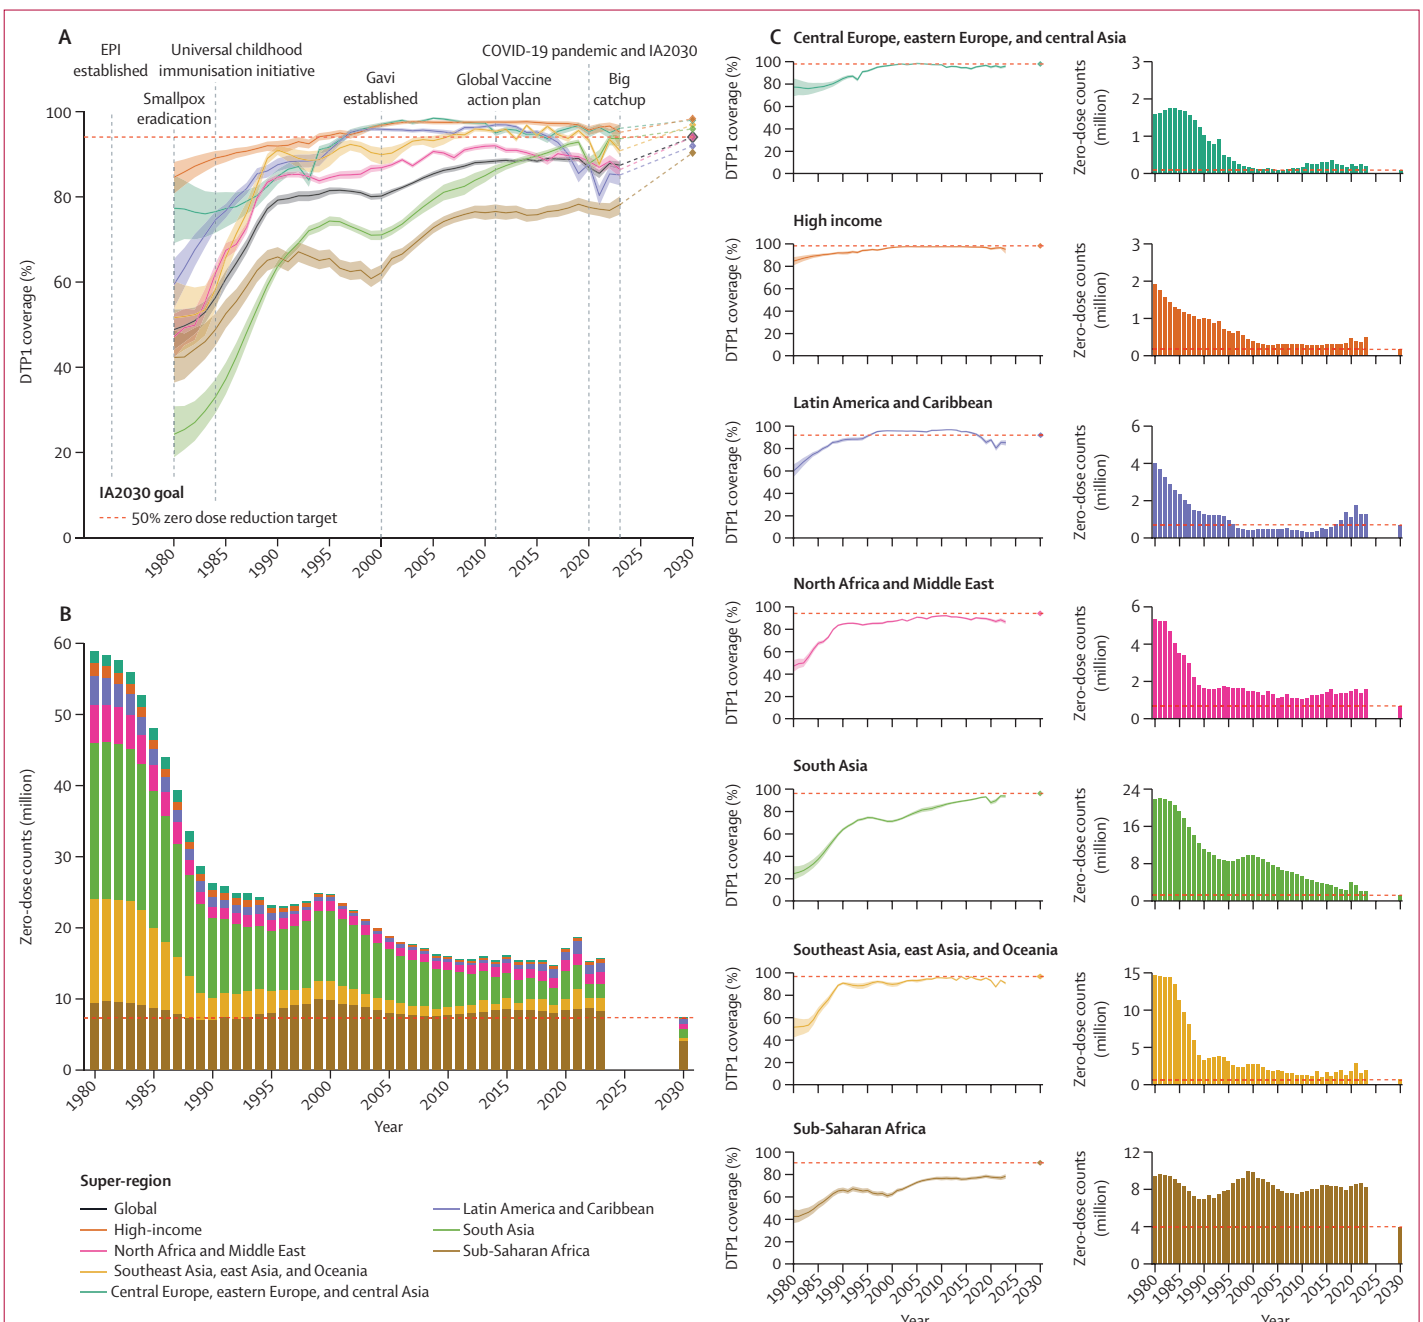

Figure 2: **Global and super-regional trends in zero-dose children over time**
(A) Global and super-regional mean DTP1 coverage estimates for the population younger than 1 year with 95% uncertainty intervals by year for 1980–2023. (B) Super-regional and global (full bars) estimates of zero-dose children by year for 1980–2023. (C) DTP1 coverage estimates and zero-dose children estimates separated by super-region. For all plots, the dashed horizontal lines and corresponding points or bars shown in 2030 represent values that would be required to meet the IA2030 50% zero-dose reduction goal. DTP1=diphtheria-tetanus-pertussis, first dose. IA2030=Immunisation Agenda 2030. EPI=Expanded Programme on Immunisation. Gavi=Gavi, the Vaccine Alliance.

immunisation programmes. However, these gains slowed or reversed between 2010 and 2019, even before COVID-19 pandemic-related disruptions in subsequent years. For MCV1, coverage declined between 2010 and 2019 for 100 of 204 countries and territories (appendix 1 pp 247–485), with the biggest decrease in the Latin America and the Caribbean super-region (90·4% [88·6–91·9] in 2010; 86·8% [85·0–88·4] in 2019). For DTP1, DTP3, and Pol3, coverage declined between 2010 and 2019 for 100, 98, and 107 countries and territories, respectively, with the largest decreases similarly in Latin America and the Caribbean (DTP1 96·5% [96·0–96·9] in 2010 and 85·4% [83·3–87·3] in 2019; DTP3 89·8% [89·0–90·6] in 2010 and 73·9% [70·9–76·3] in 2019; Pol3 87·8% [86·9–88·7] in 2010 and 76·9% [74·9–78·6] in 2019). Of 158 countries and territories with BCG in the national immunisation schedule for all years between 2010 and 2019,[41] coverage declined for 88 countries and territories over this period.

For newer vaccines, coverage gains were more consistent. Coverage for HepB3 (80·1% [95% UI 79·0–81·0]), Hib3 (70·7% [69·6–71·7]), MCV2 (67·9% [66·7–69·2]), and RCV1 (69·0% [68·0–69·9]) had begun to approach that of the original EPI vaccines by 2019 (figure 1). Global expansion of coverage for PCV3 and RotaC did not begin until the mid-2000s, but by 2019 global coverage reached 48·1% (47·3–49·0) for PCV3 and 38·8% (38·2–39·5) for RotaC.

Trends in zero-dose children, 1980–2019

Between 1980 and 2019, the global number of zero-dose children—as represented by children younger than 1 year who have not received a DTP1 dose—decreased by an estimated 74·9% (95% UI 72·1–77·3), from 58·8 million (53·4–64·2) to 14·7 million (13·8–15·6; figure 2). Most of these decreases occurred at the beginning of EPI from 1980 to 1990, when zero-dose counts decreased by 55·3% (49·1–60·5), and then following the launch of Gavi, the Vaccine Alliance when zero-dose counts decreased by another 35·4% (31·5–39·5) from 2000 to 2010.

At the super-regional level, the greatest reduction in the number of zero-dose children between 1980 and 2019 was in south Asia, with 19·5 million (95% UI 17·6–21·0) fewer zero-dose children in 2019: an 89·3% (87·9–90·4) decrease. In sub-Saharan Africa, DTP1 coverage nearly doubled between 1980 and 2019, from 42·3% (36·3–48·7) to 78·2% (76·7–79·8). However, the super-regional target population also grew by 125% during that time period, resulting in a more modest reduction of 1·41 million (0·168–2·46) fewer zero-dose children in 2019 than 1980. In 1980, 53·5% (52·3–54·7) of zero-dose children lived in just five countries: India, China, Indonesia, Pakistan, and Bangladesh. By 2019, most (52·8% [51·0–54·3]) zero-dose children still lived in only seven countries: Nigeria, India, Ethiopia, Democratic Republic of the Congo, Brazil, Somalia, and Pakistan.

Vaccine coverage trends, 2020–23: effect of the COVID-19 pandemic

Global coverage for all original EPI vaccines declined following the onset of the COVID-19 pandemic. Substantial COVID-19 pandemic-related disruptions to global coverage for the original EPI vaccines began in 2020, generally increased in 2021 and 2022, then improved but did not fully resolve by 2023 (figure 3). The greatest decreases between 2019 (the final pre-pandemic comparator year) and 2023 were estimated for Pol3 coverage (2·8 percentage points [95% UI 0·7–5·0]) and the smallest decreases for DTP1 (1·6 percentage points [0·5–2·9]).

Global coverage for most of the newer vaccines continued to expand over the course of the COVID-19 pandemic, driven by both continued introductions and scale-up (figure 1). The largest gains between 2019 (the year before the COVID-19 pandemic) and 2023 were estimated for PCV3 (14·3 percentage points [95% UI

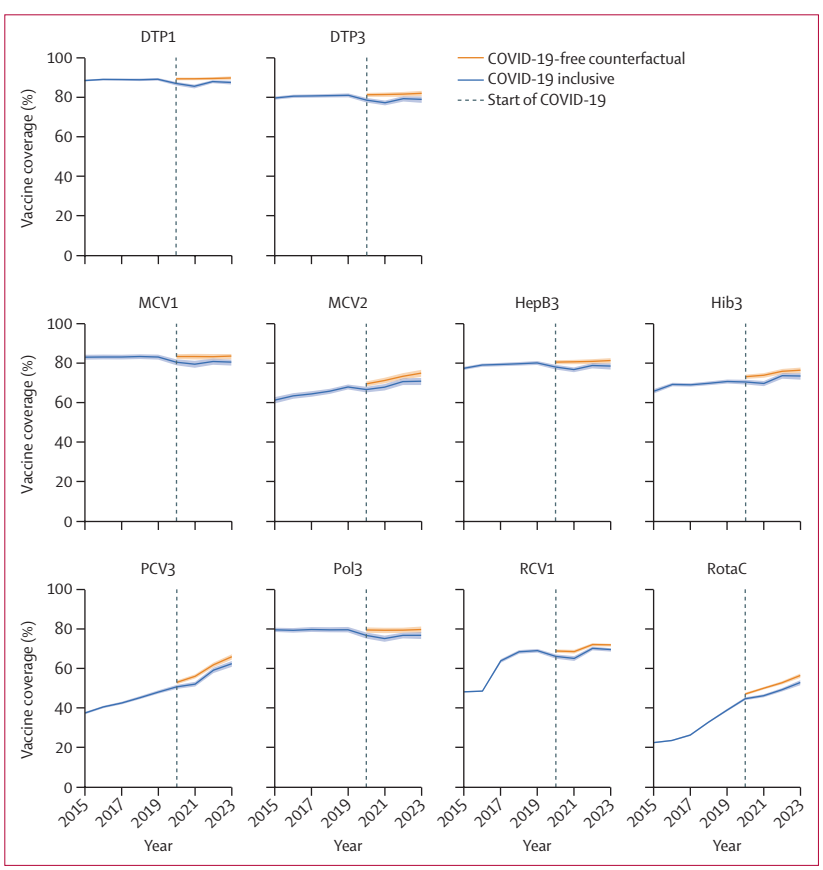

Figure 3: **Effects of the COVID-19 pandemic on global vaccine coverage**
Comparisons of global vaccine coverage estimates for the target population during the COVID-19 pandemic (blue line) versus those expected in the absence of COVID-19 pandemic-associated disruptions (orange line), with 95% uncertainty intervals. COVID-19 pandemic-related disruptions were estimated for 2020–23; coverage estimates for 2015–19 are included as a reference. DTP1=diphtheria-tetanus-pertussis, first dose. DTP3=diphtheria-tetanus-pertussis, third dose. HepB3=hepatitis B vaccine, third dose. Hib3=*Haemophilus influenzae* type b vaccine, third dose. MCV1=measles-containing vaccine, first dose. MCV2=measles-containing vaccine, second dose. PCV3=pneumococcal conjugate vaccine, third dose. Pol3=polio vaccine, third dose. RCV1=rubella-containing vaccine, first dose. RotaC=completed rotavirus series.

12·9–15·6]). All newer vaccines reached higher coverage levels in 2023 compared with 2019, except for HepB3. HepB3 is typically given as a part of a pentavalent vaccine with DTP, and global HepB3 coverage more closely mirrored DTP3 coverage and had similar disruptions during this time period. Global HepB3 coverage in 2023 remained 1·6 percentage points (0·2–3·2) lower than that seen in 2019.

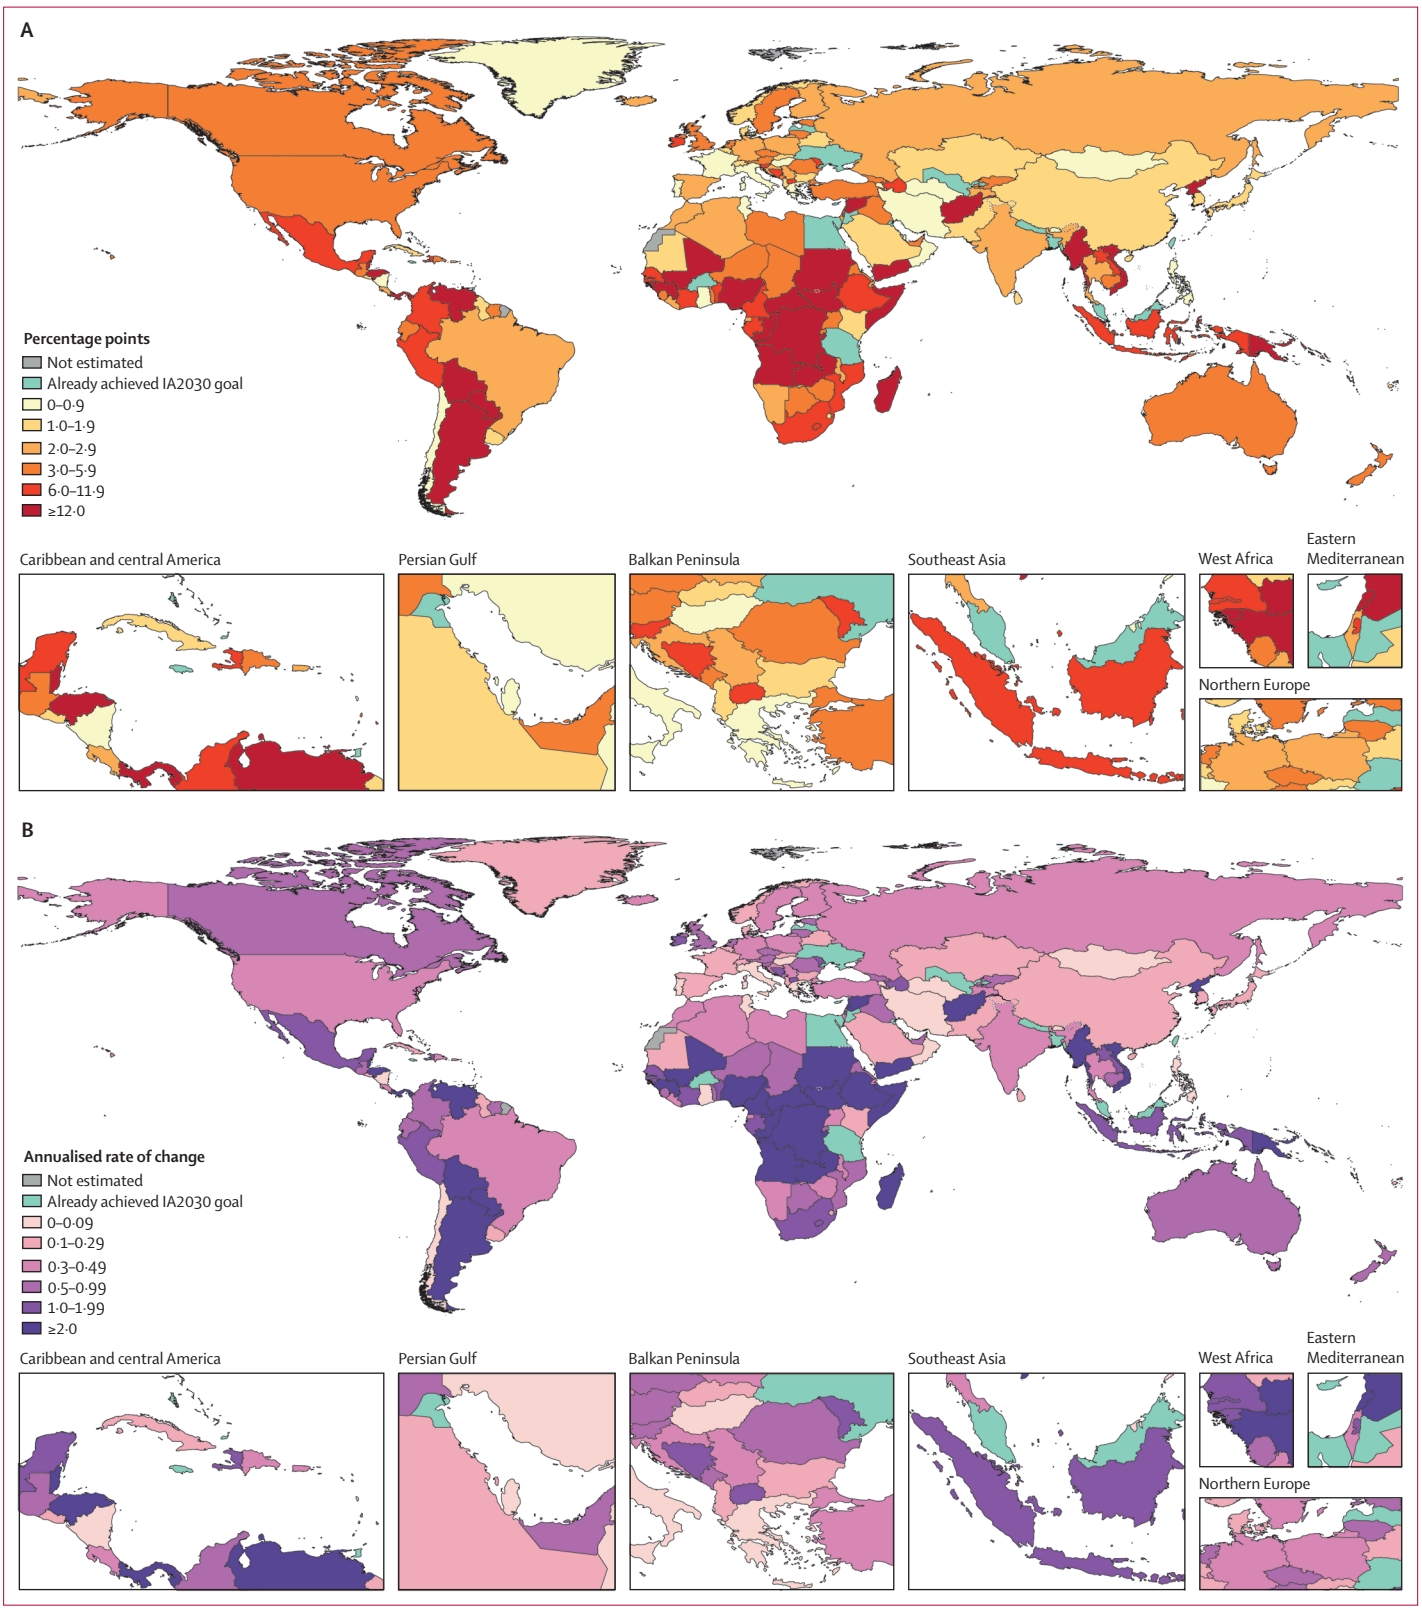
Compared with a counterfactual scenario absent COVID-related disruptions, global DTP3 coverage was 2·7 percentage points (95% UI 2·4–3·2) lower in 2020, 4·2 percentage points (3·8–4·6) lower in 2021, 2·3 percentage points (2·0–2·9) lower in 2022, and 3·1 percentage points (2·7–3·5) lower in 2023, with similar trends for MCV1, Pol3, and BCG (figure 3). The COVID-19 pandemic resulted in an estimated 15·6 million (14·4–16·9) fewer children vaccinated with DTP3 globally between 2020 and 2023, 15·6 million (14·4–17·0) fewer with MCV1, 15·9 million (15·0–17·2) with Pol3, and 9·18 million (8·20–10·2) with BCG. Although coverage continued to increase over 2020–23 for newer vaccines, these gains did not keep pace with expectations absent the pandemic (figure 3). Among the newer vaccines, the largest pandemic impacts were estimated for RotaC, with 16·6 million (15·7–17·7) fewer children vaccinated between 2020 and 2023 than if the pandemic had not occurred, followed by MCV2 (16·5 million [15·3–18·0] fewer children), PCV3 (15·8 million [15·0–16·8]), Hib3 (15·3 million [14·2–16·5]), HepB3 (14·4 million [13·1–15·7]), and RCV1 (13·4 million [12·2–14·7]).

Both the magnitude of COVID-19 pandemic-related disruptions to vaccine coverage and the degree of post-pandemic recovery varied by vaccine and super-region. Compared with the COVID-19-free counterfactual scenario, the largest single-year coverage disruptions were all estimated to have occurred in Latin America and the Caribbean, for PCV3 in 2023 and 2021, and DTP1 in 2021 (decreases of 11·6 percentage points [95% UI 9·6–13·9], 11·2 percentage points [9·7–14·1], and 11·2 percentage points [9·6–12·7], respectively). Among other super-regions, greatest single-year disruptions were for RotaC in sub-Saharan Africa in 2022 (a decrease of 7·7 percentage points [7·3–8·7]), RotaC in central Europe, eastern Europe, and central Asia in 2021 (7·2 percentage points [6·7–7·8]), and PCV3 in North Africa and the Middle East in 2021 (7·0 percentage points [6·2–8·4]). As of 2023, coverage of BCG, DTP1, DTP3, MCV1, and Pol3 had recovered to levels near expected without the COVID-19 pandemic (within 1 percentage point) only for BCG in sub-Saharan Africa and central Europe, eastern Europe, and central Asia; DTP1 in south Asia and central Europe, eastern Europe, and central Asia; DTP3 in central Europe, eastern Europe, and central Asia; MCV1 in central Europe, eastern Europe, and central Asia; and Pol3 in south Asia (appendix 1 pp 229–231, 486).

Sub-Saharan Africa as a super-region saw the greatest cumulative disruptions to vaccine coverage across 2020 to 2023 in absolute numbers for RotaC, PCV3, and Pol3 (6·96 million [95% UI 6·73–7·42], 5·31 million [5·09–5·57], and 4·94 million [4·74–5·19] fewer children vaccinated, respectively). The COVID-19 pandemic also resulted in an estimated 4·12 million (3·90–4·38) additional children missing routine MCV1 vaccination in south Asia and 4·64 million (3·59–5·64) in sub-Saharan Africa. Relative to target population size, cumulative disruptions were greatest in Latin America and the Caribbean, for PCV3, RotaC, and DTP3, with cumulative percent losses in children vaccinated of 9·4% (8·2–10·6), 7·8% (6·7–8·9), and 7·6% (6·5–8·8), respectively. Other notable relative disruptions occurred in north Africa and the Middle East for PCV3 (a cumulative loss of 5·5% [5·1–6·0]), sub-Saharan Africa for RotaC (a cumulative loss of 4·7% [4·5–5·0]), and southeast Asia, east Asia, and Oceania for Pol3 (a cumulative loss of 4·3% [3·9–4·6]). Greatest cumulative absolute and proportional COVID-19 pandemic disruptions tended to occur in Latin America and the Caribbean, sub-Saharan Africa, and south Asia (appendix 1 p 486).

Trends in zero-dose children, 2020–23: impact of the COVID-19 pandemic and progress needed to reach the IA2030 target of 50% reduction by 2030

The COVID-19 pandemic has reversed previous gains in reducing zero-dose children globally. As of 2023, there were 15·7 million (95% UI 14·6–17·0) zero-dose children worldwide, compared with 14·7 million (13·8–15·6) in 2019: a 2·9% (2·6–3·2) increase. This reversal follows a long period of progress, during which global zero-dose counts decreased from 58·8 million (53·4–64·2) in 1980 to 14·7 million (13·8–15·6) in 2019. The global number of zero-dose children rose to 18·6 million (17·6–20·0) in 2021 before declining, but still remaining above pre-pandemic levels in 2022 and 2023. To reach the IA2030 zero-dose target, the global number of zero-dose children would need to be halved from 2019 levels to 7·35 million (6·92–7·82) by 2030 (figure 2; appendix 1 pp 232–237). This would equate to increasing global DTP1 coverage from 87·4% (86·4–88·3) in 2019 to 94·0% (93·6–94·3) in 2023. Between 2020 and 2023, COVID-19 pandemic-related disruptions to DTP1 coverage resulted in a total of 12·8 million (11·7–14·0) additional zero-dose children over these 4 years. South Asia was the only super-region whose DTP1 coverage in 2023 neared levels expected in absence of the pandemic (within 0·8 percentage points [–0·9 to 1·9]). As of 2023, 51·1% (47·7–53·6) of all zero-dose children lived in eight countries, primarily in sub-Saharan Africa and south Asia (Nigeria, India, Democratic Republic of the Congo, Ethiopia, Somalia, Sudan, Indonesia, and Brazil). Compared with 2019, this distribution reflects recent rising numbers of zero-dose children in Sudan and Indonesia and decreases in Pakistan due to rising coverage (appendix 1 pp 232–237).



(Figure 4 continues on next page)

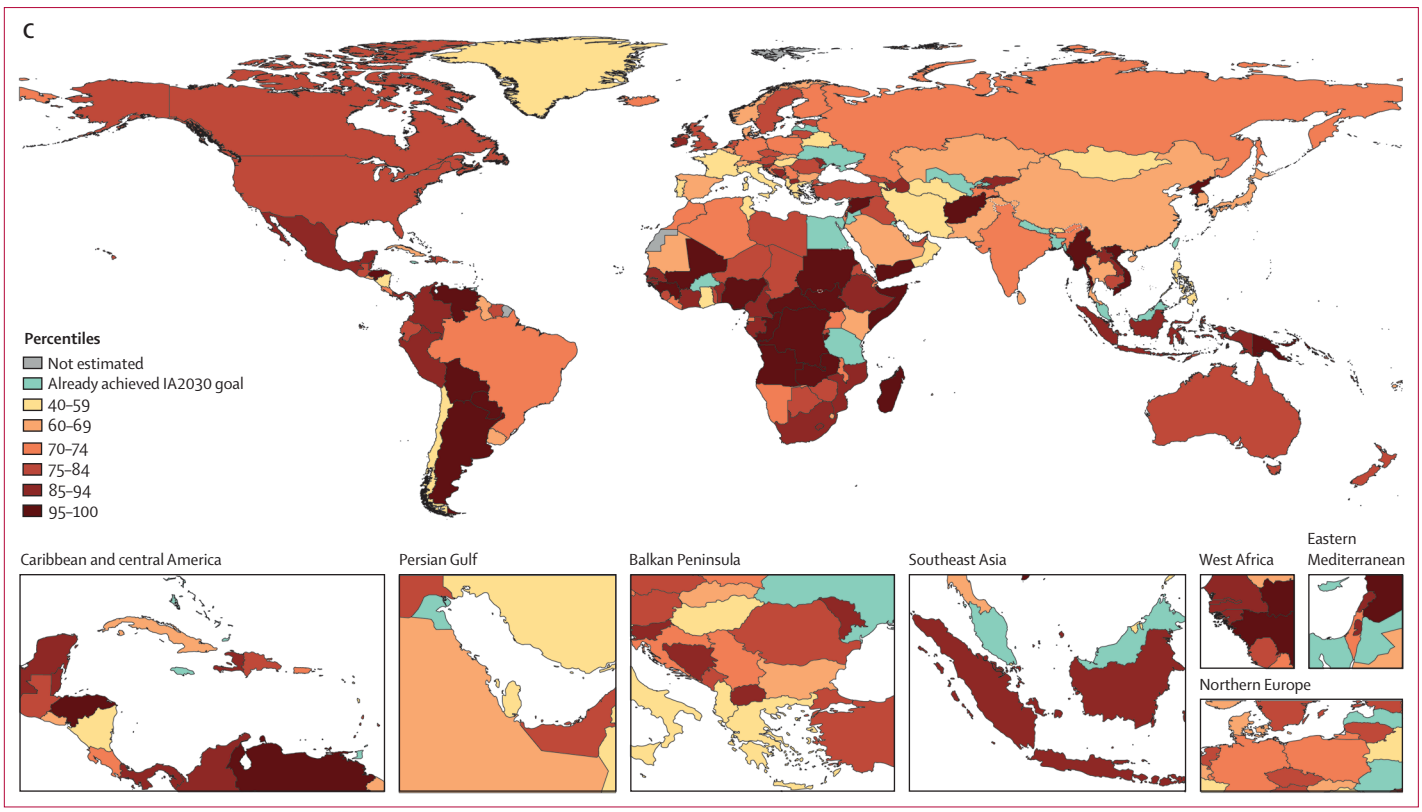


Figure 4: **Change required to reach the IA2030 goal of 50% reduction in zero-dose children**
(A) Map of percentage point change from DTP1 coverage for children younger than 1 year in 2023 required by each country to reach the IA2030 goal of a 50% reduction in zero-dose children by 2030. (B) The AROC in DTP1 coverage from 2023 required to reach the 50% reduction in zero-dose children by 2030. (C) The AROC in DTP1 coverage required between 2023 and 2030 to achieve the same goal, expressed as a percentile of the distribution of all country-level DTP1 coverage AROCs from all 7-year periods between 2000 and 2019. DTP1=diphtheria-tetanus-pertussis, first dose. AROC=annualised rate of change. IA2030=Immunization Agenda 2030.

Under a scenario in which all countries and territories contribute equally to the IA2030 zero-dose reduction goal, accounting for anticipated population changes, 51·2% (95% UI 35·9–63·9) of the additional zero-dose children (8·34 million [7·12–9·64]) needed to be reached by vaccination in 2030 compared with 2023 would live in eight countries: Nigeria, India, Democratic Republic of the Congo, Sudan, Somalia, Indonesia, Ethiopia, and Viet Nam (appendix 1 pp 232–237). The largest absolute reductions in zero-dose children over 2023–30 would be required in sub-Saharan Africa and south Asia (4·28 million [3·46–5·10] and 1·33 million [1·07–1·61], respectively). The super-regions of Latin America and the Caribbean and central Europe, eastern Europe, and central Asia have historically achieved the DTP1 coverage levels that would be needed to reach their IA2030 targets (91·9% [90·7–92·9] and 98·0% [97·5–98·4], respectively). For south Asia, 95·9% (95·5–96·3) of DTP1 coverage would be required by 2030, 2·2 percentage points (1·8–2·5) higher than the highest historical coverage. Sub-Saharan Africa would require 90·3% (89·6–91·0) of DTP1 coverage, 12·1 percentage points (11·4–12·8) higher than highest historical coverage in the super-region. Together, these two super-regions account for 65·1% (62·8–68·6) of the total global reduction in zero-dose children required between 2023 and 2030.

At the country level, 18 of 204 countries and territories had reached a 50% reduction in zero-dose children by 2023 (figure 4). Among those countries and territories with birth cohorts of at least 10 000, Tanzania, Jordan, and Malaysia had the greatest percentage reductions in zero-dose children, whereas Trinidad and Tobago, Ukraine, and Jordan had the greatest percentage point gains in DTP1 coverage (appendix 1 pp 232–237, 247). Conversely, compared with 2023 levels, 40 (20%) countries and territories require a more than 10 percentage point increase in DTP1 coverage by 2030, and these account for 62·4% (95% UI 52·4–71·4) of the total reduction in global zero-dose children required over this time. Many countries and territories would need to substantially outpace historical trends to reach 2030 zero-dose targets. Of 186 countries and territories not meeting this target by 2023, only 18 (10%) require a future AROC below the median of historical AROCs, and nearly half (80 [43%]) would need to exceed the 80th percentile of historical AROCs (figure 4C). Among the eight countries needed to contribute the largest reductions in zero-dose children (4·22 million [51·2%]

of 8·34 million), seven would need to exceed the 80th percentile of past DTP1 AROCs (Somalia, Sudan, Democratic Republic of the Congo, Viet Nam, Nigeria, Ethiopia, and Indonesia), six would need to exceed the 90th percentile (Somalia, Sudan, Democratic Republic of the Congo, Viet Nam, Nigeria, and Ethiopia), five would need to exceed the 95th percentile (Somalia, Sudan, Democratic Republic of the Congo, Viet Nam, and Nigeria), and two would need to exceed the 99th percentile (Somalia and Sudan). For these countries, improvements in DTP1 coverage would need to outpace almost any gain that any country in the world has achieved since 2000. As of 2019, 38 countries and territories had achieved 99% DTP1 coverage or greater, but this number decreased to 24 countries and territories by 2023.

Forecasting progress towards IA2030 90% coverage targets for life-course vaccines

To assess progress towards the IA2030 goals of 90% global coverage for life-course vaccines, we forecasted vaccine coverage for three scenarios (reference, better, and worse). By 2030, globally, vaccine coverage under the reference scenario is forecasted to reach 81·3% (95% UI 79·5–82·7) for DTP3 (2·4 percentage points [0·6–3·8] higher than in 2023), 71·1% (69·6–72·5) for PCV3 (8·7 percentage points [7·1–10·1] higher than in 2023), and 76·0% (73·7–78·1) for MCV2 (5·2 percentage points [2·8–7·2] higher than in 2023; figure 5). In contrast, under the worse scenario, global vaccine coverage could decline between 2023 and 2030 to 68·9% (66·9–70·4) for DTP3, 59·3% (57·4–60·9) for PCV3, and 62·7% (60·1–65·1) for MCV2. Alternatively, under the better scenario, global vaccine coverage could increase to 91·2% (89·4–92·7) for DTP3, 85·7% (84·0–87·3) for PCV3, and 85·3% (83·1–87·1) for MCV2. Even under the better scenario, only DTP3 coverage (historically higher than the more recently introduced MCV2 and PCV3) is forecasted to reach 90% global coverage. However, reference scenario forecasts varied substantially by GBD super-region (appendix 1 p 487).

85 of 204 countries and territories are estimated to have reached 90% coverage by 2023 for DTP3, 56 countries for PCV3, and 57 countries for MCV2. Under the reference scenario, an additional 23 countries and territories are forecasted to reach 90% coverage for DTP3 by 2030 (108 of 204 total), 27 countries for PCV3 (83 of 204 total), and 34 countries for MCV2 (91 of 204 total; appendix 1 p 488). Notably, only the high-income super-region is expected to reach or retain at least 90% coverage for the three life-course vaccines by 2030 under the reference scenario. Under the better scenario, these achievements would improve to 186 of 204 countries and territories for DTP3, 171 countries for PCV3, and 161 countries for MCV2. Under the worse alternative scenario, all countries and territories that had achieved 90% coverage for DTP3, PCV3, and MCV2 by 2023 would drop below this target by 2030.

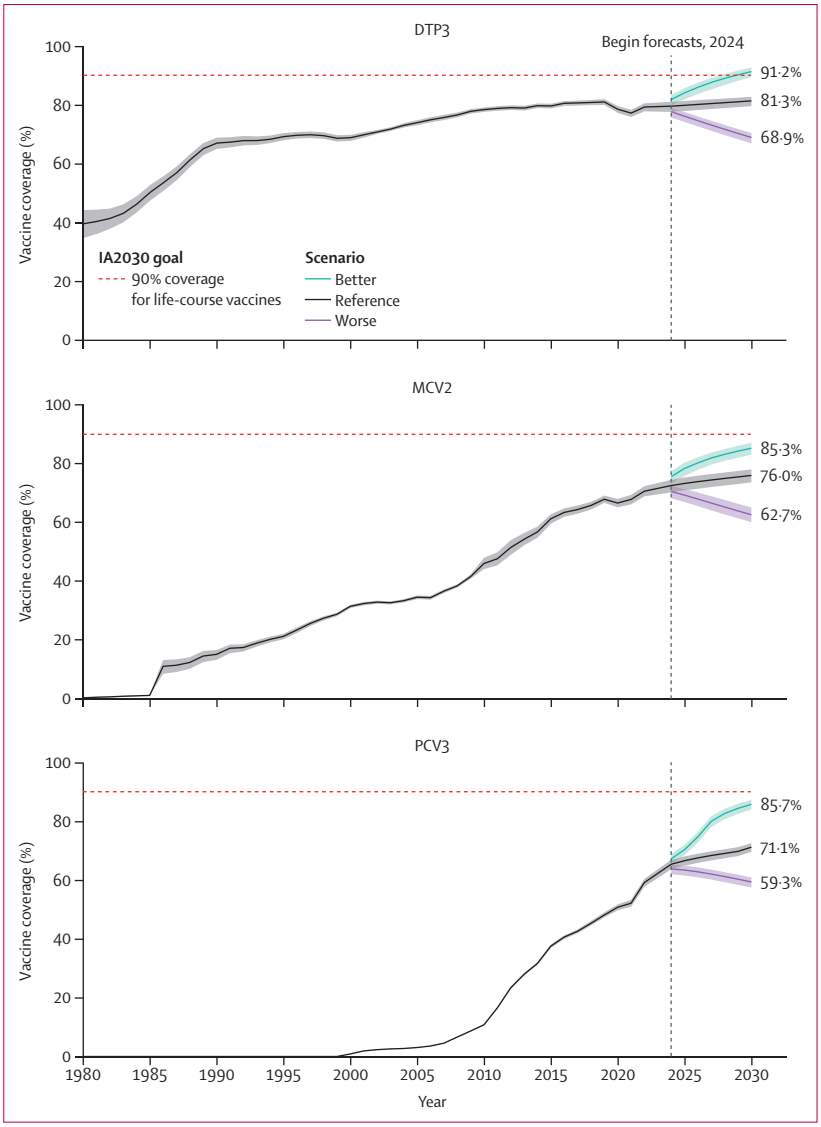

Figure 5: **Forecasted global vaccine coverage**
Historical mean global vaccine coverage for 1980–2023 and forecast coverage for the target population for 2024–30 for DTP3, MCV2, and PCV3. Forecasts are displayed for the reference scenario along with better and worse scenarios, as well as 95% uncertainty intervals for all scenarios. Better and worse scenarios are calculated with the 85th and 15th percentiles of past rates of change in coverage, respectively. For all plots, the dashed horizontal line indicates the coverage required to meet the IA2030 goal of 90% coverage for life-course vaccines. DTP3=diphtheria-tetanus-pertussis, third dose. MCV2=measles-containing vaccine, second dose. PCV3=pneumococcal conjugate vaccine, third dose. IA2030=Immunization Agenda 2030.

Discussion

Overview of main findings

The first five decades of EPI have fundamentally transformed the landscape of global health through the vaccination of more than four billion children, a doubling of coverage for the original EPI vaccines, the successful introduction and scale-up of new life-saving vaccines, and a three-quarters reduction in the number of zero-dose children since 1980. In recent years, however, this progress has stalled and in some areas of the world reversed—a period of stagnation that began in the decade preceding

the COVID-19 pandemic for the original EPI vaccines. We estimate that the COVID-19 pandemic resulted in tens of millions of additional children missing doses from across these 11 routine childhood vaccines since 2020, including an additional 12·8 million zero-dose children, compared with expectations had the pandemic not occurred. Although vaccine coverage in 2023 remained lower than expected in the absence of the pandemic, there are signs of recovery across many vaccines and super-regions, thanks to the concerted efforts of local, national, regional, and global vaccine advocates.

Five decades on, therefore, the promise of EPI—to extend the life-saving benefits of vaccines to all children around the world—has been only partially fulfilled. As these results underscore, global vaccine coverage targets cannot be met without transformational improvements in equity.

Challenges to sustaining and improving on EPI's successes

Despite the remarkable public health successes achieved around the globe by routine childhood vaccination over the past 50 years, efforts to preserve and extend these gains face considerable challenges. Inequalities in coverage, including large numbers of children who remain unvaccinated, persist across and within regions, countries and territories, and communities.[8,9,14,15,53,54] As the present findings highlight—although steep drops in counts of unvaccinated zero-dose children took place over the past five decades in nearly all regions of the world—these successes were not matched in sub-Saharan Africa, where declines were considerably less pronounced. Zero-dose numbers even increased in some areas during certain periods: in sub-Saharan Africa and south Asia during the 1990s, and in Latin America and the Caribbean and in central Europe, eastern Europe, and central Asia after 2010. As of 2023, more than 50% of the world's zero-dose children lived in just eight countries, characterised variously by weak health systems, large birth cohorts, geographical isolation, erosion of vaccine confidence, and exposure to conflict.[9] Indeed, our results show that Sudan was close to reaching a 90% DTP1 coverage in 2019, but with civil war arising in 2023 as per Armed Conflict Location and Event Data, coverage nearly halved. Our estimates reflect complex interactions between these interrelated factors and underscore the need for targeted interventions tailored to each circumstance.

Effect of the COVID-19 pandemic

Starting in 2020, much of the long-term progress achieved in the global campaign to reduce mortality and morbidity through routine immunisation was halted or reversed during the massive global upheaval caused by the COVID-19 pandemic and has not fully recovered since. The crisis and its cascading effects placed extraordinary pressure on health systems and providers, immunisation supply chains, and health spending, which—combined with physical distancing and stay-at-home measures—severely limited the ability of health workers and those in need of care to provide and access services.[55] Other studies found during the height of the pandemic that coverage inequalities within regions grew during the pandemic.[56] Even after these measures were lifted, the effects of the COVID-19 pandemic had been ongoing. Even as late as 2023, 84% of countries and territories were still reporting some disruption to health services, and immunisation ranked third highest in terms of services disrupted.[11,57] Our estimates show that between 2019 and 2023, global numbers of zero-dose children rose to their highest levels in 2021 at 18·6 million, with counts in 2023 remaining at 15·7 million, 989 000 more than in 2019. In addition, global coverage decreased for all the original EPI vaccines between 2019 and 2023, with the greatest declines occurring in 2021.

Our analysis suggests that the COVID-19 pandemic, along with disruptions in immunisation services due to recent conflicts, has resulted in tens of millions of additional children globally missing routine vaccines since 2020, increasing their risk for preventable disease and death. In 2022, 33 countries and territories reported sizeable measles outbreaks, compared with 22 countries and territories in 2021. In addition, increasing numbers of wild-type polio cases were reported in Pakistan and Afghanistan, and new outbreaks of wild-type polio occurred in Malawi and Mozambique in 2024. A resurgence of diphtheria was also reported, with outbreaks in Bangladesh, Nepal, Nigeria, Pakistan, Venezuela, and Yemen.[58,59] These disease trends were already on the rise before the COVID-19 pandemic[60] and reflect long-standing inequalities in vaccine coverage but pose a global risk, including to high-income countries and territories where coverage has stagnated or declined in recent years.

Despite these challenges, the effect of the COVID-19 pandemic on vaccination coverage could have been even greater. In a previous analysis using partial-year data from the first months of the pandemic, Causey and colleagues estimated 2020 global DTP3 coverage at approximately 76·7%, which is 7·7 percentage points lower than was expected in the absence of the pandemic.[18] In contrast, with the benefit of time to account for delayed reporting from many countries and data sources, our present estimates using more complete data indicate that global DTP3 coverage in 2020 was 78·5%, or just 2·7 percentage points lower than expected without the pandemic. The mitigation of the pandemic's influence on vaccine coverage reflects the tremendous efforts of vaccinators worldwide and the concerted and coordinated efforts on the part of immunisation organisations to continue the delivery of essential health services in extremely challenging circumstances.[61,62]

Challenges and opportunities in different zero-dose populations

Due to the known challenges to vaccine delivery posed by poverty, lack of accessibility, and the presence of civil or

regional conflicts,[53,54,63,64] research and policy work focused on zero-dose children has concentrated primarily on the urban poor or those living in remote or conflict-affected areas.[65–67] Given the consistently strong relationship between mothers' education and whether their children are immunised,[54,68] there is also growing awareness of the effect of the social construct of gender on vaccination coverage.[15] The low societal status of women—manifesting in a lack of resources, agency, and power—is increasingly shown to be one of the most universal factors adversely affecting equitable childhood immunisation.[68–71] Gender inequalities and socioeconomic factors—including migration status, poverty, ethnicity or caste, access to family planning, and geographical setting—intersect to depress childhood immunisation outcomes for under-resourced populations.[68,72]

Countries and territories with the highest zero-dose burdens face a demographic double challenge: although the global birth cohort is projected to shrink by 1·6% globally between 2023 and 2030,[73] many high-burden countries and territories will have substantial growth in their vaccination target populations. Nigeria, Ethiopia, and Democratic Republic of the Congo—which collectively contain 26·8% (95% UI 24·2–28·8) of global zero-dose children as of 2023—will see birth cohorts expand by 16·1%, 10·6%, and 5·9%, respectively, during this period. These demographic trends translate directly into increased resource requirements for achieving vaccination targets or even maintaining present coverage levels. These population pressures, combined with existing health system constraints, underscore the need for vaccination strategies that scale more rapidly than population growth in these settings, including enhanced outreach services, simplified delivery models, and innovative workforce approaches. Beyond population growth challenges, even successful 50% reductions in zero-dose counts across all countries and territories would still leave 26 countries with less than 90% DTP1 coverage in 2030, reflecting the magnitude of current inequalities in coverage.

The diversity of challenges and barriers leading to the failure to immunise varies broadly from country to country and community to community, highlighting the need for new and tailored solutions.[65–67,74] Strategies such as the Identify-Reach-Monitor-Measure-Advocate framework[75] have been proposed as a way to develop and deliver community-specific plans to reach zero-dose children. Some key strategies that have yielded improved vaccine uptake include awareness and education, communication, mobility of vaccination units, community engagement, motivational incentives, positive reinforcement, and assurance of vaccine safety.[76,77] These efforts must be supported by strong evidence and data, including robust, timely, and local estimates of coverage and a better understanding of the location and characteristics of zero-dose children within each country.[78]

Vaccine hesitancy

Although some of the COVID-19 pandemic-specific challenges to vaccination have receded, several key challenges persist—including increasing disparities in resource-constrained, conflict-affected, or politically-volatile countries and territories;[79,80] intensification of migration and displacement; and climate-related crises.[10,11] An additional challenge to progress has been the threat of growing vaccine hesitancy. Deriving from many complex origins, vaccine misinformation[81,82] and scepticism were already challenges before the pandemic, identified by WHO in 2019 as one of the ten leading threats to global health.[23,83,84] The COVID-19 pandemic, which in many areas bred declining trust in public health institutions[85] and polarised opinions about the necessity and safety of vaccination against COVID-19,[82] has had varying effects on public perceptions regarding the importance of routine childhood vaccination and willingness to vaccinate. A 2023 global analysis reported that vaccine hesitancy prevalence ranged from a low of 13·3% in the WHO region of the Americas to a high of 27·9% in the Eastern Mediterranean region,[86] and even higher in select African countries.[87] In the USA, most parents remained convinced of the benefits and effectiveness of childhood vaccines between 2020 and 2022, with confidence levels ranging from 89·5% to 92·5%, although concerns about vaccine safety and side-effects increased over that time,[88] and kindergarten vaccine exemption rates in 2023–24 were the highest ever reported.[89]

Although overall confidence in routine childhood immunisation remains relatively high, the COVID-19 pandemic clearly exposed a vein of public distrust regarding health policy that is likely to influence public perception of childhood vaccines into the future.[84] Strategies to improve vaccine confidence include bolstering scientific literacy to protect against an erosion of trust in science, implementing targeted public health campaigns to promote routine childhood immunisation, including community input in scientific research and policy making, engaging with community and religious leaders as advocates for immunisation, and elevating and equipping health-care providers—who remain the most trusted voices on vaccination—to have impactful conversations about decisions to immunise.[25,83,84]

Looking forward to WHO's Immunization Agenda 2030 targets

To track progress in vaccination across the life course, IA2030 targets include halving the global number of zero-dose children and achieving 90% global coverage of DTP3, PCV3, MCV2, and HPVc by 2030 (HPVc was not included in the present analysis due to the lack of currently available data). These targets were ambitious at the time of their creation and present even greater challenges now, following the effect of the COVID-19 pandemic on global vaccination rates. For many countries

and territories, the IA2030 targets might be achievable, but might require acceleration of progress. In the countries, territories, and super-regions with the largest numbers of non-immunised and under-immunised children, achieving these targets would require extraordinary improvements in vaccination coverage. By 2023, numbers of zero-dose children remained higher than in 2019 in all super-regions except south Asia. Our forecasts indicate that achieving the ambitious IA2030 goal of 90% global coverage by 2030 for each of the life-course vaccines DTP3, PCV3, and MCV2[28] is also unlikely. Moreover, coverage disparities seen in 2023 for DTP3 and MCV2 will persist in 2030, with coverage rates in sub-Saharan Africa remaining substantially below other super-regions.

Our analysis suggests similar challenges in meeting zero-dose reduction goals. Even if optimistic forecast scenarios were to be achieved, or if all countries and territories were to meet zero-dose reduction targets, these results suggest that substantial geographical disparities will persist in 2030—particularly for DTP3 and MCV2. For PCV3, coverage disparities will lessen due to ongoing introductions and scale-up, though would nevertheless persist even in the better scenario.

The success of the first 50 years of EPI has only been possible due to broad and sustained cooperation at all levels, from local health workers to national immunisation programmes to regional and global partnerships. At the global level, WHO coordinates and provides vaccination guidance for all countries and territories and plays a central role in data collection. For example, this study relies on 49 710 vaccine-country-years of data reported by country offices that were collected, collated, and reported annually by WHO through the JRF,[31] and these estimates additionally benefit from contextual insights regarding these coverage data generated by WUENIC.[49] Gavi supports qualifying countries and territories in strengthening their immunisation programmes, and currently provides vaccines for routine immunisation in 54 countries and territories while they work towards more sustained domestic financing strategies.[90] This report shows the substantial scaling up of newer vaccines in low-income and middle-income countries and territories, and Gavi has had a central role in supporting these country-led introductions. The US Agency for International Development (USAID) has also had a key role in monitoring vaccine coverage in low-income and middle-income countries through the DHS, which provide a major source of population-based data about vaccination rates at national and local scales. This study includes data from 313 DHS sources, which represent over half (50·2%) of all survey data sources included from low-income and middle-income countries.

With recent shifts in the global immunisation funding environment—including the large-scale termination of USAID-supported programmes, announced cuts to US funding for Gavi and WHO, and broader reductions in global commitments to developmental assistance for health—[91–94] the historical and future progress of vaccination programmes is at risk. With reduced fiscal space, any further new vaccine introductions are in jeopardy, vaccination coverage rates might decrease, and the risk of vaccine-preventable disease is heightened. In this time of risk, accurate estimates of vaccine coverage become even more important. With the closure of the DHS programme, strategic and coordinated efforts to assess coverage through targeted surveys and support for country immunisation data systems will be needed.

Childhood immunisation is an outstanding investment with excellent returns in health and economic benefits, across countries and territories of all income levels.[95–98] Proposed reductions in immunisation spending are likely to disproportionally affect low-income and middle-income countries, but high-income countries and territories are also likely to incur health-care costs associated with new and more frequent disease outbreaks.[99,100] Europe saw its highest number of measles cases in 2024 since 1997, and the first measles-related death in the last decade in the USA occurred in an unvaccinated child as part of a measles outbreak in Texas in early 2025.[101] Without concerted efforts to bolster immunisation rates in all countries and territories, these risks will continue to increase.[102]

Due to ongoing uncertainty about the final scope and magnitude of proposed funding cuts, the effects of these decisions are not considered in our forecasts of the IA2030 life-course vaccines. However, if these proposed funding cuts are fully implemented, the forecasts presented here, which already show that global coverage is not on track to reach the IA2030 targets, are likely to be too optimistic. Similarly, the scenario of equal contribution presented here with all countries and territories contributing proportionally to 50% zero-dose reduction targets becomes even more unlikely given the disproportionate effects of additional funding constraints. Nevertheless, it is important to note that any gains in coverage and reduction of existing disparities—even if they fall short of the ambitious goals set by IA2030—would still result in massive public health gains. Each percentage point increase in global vaccination coverage represents protection for millions of additional children against deadly diseases. This perspective does not diminish the importance of ambitious targets, but rather emphasises the substantial value of continued, incremental progress in all settings.

Limitations

Our present estimates of routine childhood vaccination coverage are limited by various methodological considerations. First, although we applied models designed to adjust for bias in vaccine coverage data, we were not able to account for all potential sources of bias. Displaced or otherwise disenfranchised individuals

might be under-represented in the data. Survey data might not accurately capture effects such as migration, catch-up vaccination, and differential survival by immunisation status across the age cohorts on which we based our analyses. Both surveys and country-reported data might be limited in their ability to assess immunisation rates in conflict-affected areas, leading to potential overestimation in the absence of data from these locations and time periods. Reporting of surveys and country-reported data was in many instances delayed by the COVID-19 pandemic; while the timing of this study has allowed for catch-up in reporting, decreases in survey participation rates and other forms of reporting biases during that time might have also occurred and are not reflected in this study. Data that relied on parental or observer recall are subject to recall bias, which we did not to adjust for, based on evidence indicating highly variable effects of recall bias on coverage estimates.[103–105] We were also not able to systematically account for methodological variability across surveys. We provide statistical uncertainty from our modelling framework to reflect confidence in the reported coverage values. Although ST-GPR and MR-BRT partially mitigate the limitations of data sparsity in select locations, estimates in such areas might show greater uncertainty. In this analysis, we produce estimates for all national locations included in the GBD 2023 study, including those for which data are sparse and estimates are uncertain. This approach follows the principles of the GBD study,[38] which prioritise comprehensive comparisons and recognise that the absence of an estimate often results in the exclusion of that location from strategic planning and policy decisions. Although we aim to select covariates plausibly linked to vaccination coverage, our models do not allow for potential interactions between covariates such as SDI and disruption magnitude or conflict. Due to the multistep nature of ST-GPR, these limitations are most likely to affect data-sparse locations, where estimates are more heavily informed by covariates and regional trends. Similarly, although our modelled estimates of administrative bias allow variation in bias over time where multiple overlapping coverage observations from survey and country-reported data are available, estimates of trends in bias might be less reliable in data-sparse locations, or where abrupt discontinuities in administrative reporting methodology occur (eg, when countries switch to using electronic systems such as DHIS2 for ascertaining vaccine delivery counts).

Second, our reliance on DTP1 coverage as a measure of zero-dose children, although standard practice,[9,106] could overestimate the number of those who do not receive any childhood vaccinations, as children might in some cases receive other vaccinations even after missing DTP1. Similarly, our understanding of trends in zero-dose children rely on estimates and forecasts of populations. Following standard GBD practices, we did not account for uncertainty in these population estimates, and the uncertainty intervals for zero-dose and other counts included here thus represent uncertainty only in the associated coverage estimates. The uncertainty intervals for these count-based estimates, therefore, may underestimate the true degree of uncertainty in these measures.

Third, our analysis does not include data on vaccinations that take place outside EPI-designated routine childhood immunisation schedules, such as vaccinations administered in limited immunisation campaigns targeting specific populations or administered through private markets (except for selected private vaccinations in China, which are included in our analysis). Due to a lack of comprehensive data, our analysis does not account for catch-up vaccination activities, including global efforts through WHO's Big Catch-Up initiative to reach children who missed routine immunisations during the COVID-19 pandemic.[58] Although age-specific survey data can provide some insight into catch-up vaccination, comprehensive administrative data are not available to inform such models. Additional efforts are needed to collect data and develop analytic methods to estimate coverage across all ages, including the effect of catch-up activities. Even so, catch-up activities represent a stop-gap measure that cannot replace improvements to routine health-care services. Our results show that disruptions due to COVID-19 have had long-lasting and persistent effects on routine services, which serve as the foundation for strong immunisation programmes.

Fourth, our analysis estimates the size of the effect of the COVID-19 pandemic on vaccine coverage by first estimating coverage in the absence of stockouts or any other disruptions to coverage. We then assume that, absent the COVID-19 pandemic, each country would have had the average degree of coverage disruption due to stockouts or other factors, as was observed from 2015 to 2019. This year range was selected to try to reflect the most recent patterns in disruptions, but nevertheless it is challenging to disentangle the ongoing historical trends from the impacts of the COVID-19 pandemic, and it is not necessarily the case that recent disruption trends would have continued apace. In particular, for countries and territories where large disruptions were common before the COVID-19 pandemic or coverage levels were changing rapidly, we may overestimate or underestimate COVID-19 pandemic-related impacts. Therefore, we have presented the results of this post-hoc analysis in aggregate at super-region and global levels only. In this counterfactual estimation, we do not account for the effect of delays in the introduction of new vaccines that might have occurred due to the COVID-19 pandemic. For these newer vaccines, it is therefore likely that we might underestimate the global effect of the pandemic.

For more on **DHIS2** see https://dhis2.org/

Fifth, we imputed disruption estimates for countries and territories without country-reported data during the COVID-19 pandemic, using vaccine-specific and

year-specific distributions of disruption magnitudes from locations with available data. As our results show, however, actual disruption magnitudes varied widely. Our results in these country-vaccine-years might thus reflect either overestimation or underestimation of actual disruptions. In particular, many high-income countries and territories have incomplete data reporting during the COVID-19 pandemic and estimates of COVID-19 pandemic-related disruptions in these locations should be interpreted with caution.

Sixth, our process for estimating coverage of newer vaccines first as ratios relative to a reference vaccine (DTP3 for HepB3, Hib3, PCV3, and RotaC, and MCV1 for MCV2 and RCV1) constrains our estimates of these newer vaccines to be lower than that of their respective reference vaccines. For vaccines given in combination with the reference vaccine (eg, RCV1 and MCV1, or Hib3 and DTP3), or where these constraints are implied by definition (eg, MCV2 < MCV1, or DTP3 < DTP1), this assumption is appropriate. PCV and rotavirus vaccines, are typically given on the same schedule as DTP; however, coverage could exceed that of DTP3 in rare cases, particularly in the setting of intensive scale-up or vaccine-specific disruptions to DTP3 coverage. Future improvements to this work could consider independent modelling of PCV3 and/or RotaC coverage.

Although not a focus of the present analysis, characterising within-country differences in coverage is also important. Assessing coverage by crucial sociodemographic factors—eg, by geography at subnational scales, wealth, education, women's status, refugee status, and race and ethnicity—can help identify persistent disparities in routine childhood vaccination masked by the national overview estimates presented here. Similarly, although HPVc is one of IA2030's 90% life-course vaccine coverage targets and has been recommended globally by WHO since 2009,[107] we were not able to generate estimates or forecasts of HPVc coverage due to the lack of currently available survey data in most settings. Additional work will be needed to generate coverage estimates for HPVc and other vaccines not included here, using rigorous statistical frameworks that can leverage both survey and administrative data sources. In this report, we did not measure rates of under-vaccinated children, those who have received only some but not all vaccine doses in their vaccination schedule, or assess patterns in the timeliness of vaccination. Comprehensive estimates of the full spectrum of vaccination, beyond the coverage metrics presented here, would improve understanding of population susceptibility and risks of disease outbreaks.

Conclusions

Over the past 50 years, EPI has achieved extraordinary success in the urgent public health campaign to immunise the world's children against life-threatening diseases. The next 50 years will require sustained efforts at global, regional, national, and community levels to successfully preserve and extend existing gains. Enduring coverage inequities and the persistent effects of the COVID-19 pandemic only serve to underscore the importance of advancing routine childhood vaccination, one of the most powerful public health interventions known.

Current trends and forecasts, along with proposed reductions to global immunisation financing, suggest that reaching the ambitious goals of IA2030—aimed at reducing mortality and morbidity from vaccine-preventable diseases for everyone, everywhere—is unlikely to be realised unless the global community redoubles its commitment to equitable and universal vaccination strategies. Effective programmes and policies must integrate vaccination services into revitalised primary health-care systems, focus on context-specific and community-driven immunisation strategies, increase and optimise investment in vaccination, and prioritise community-led approaches to build vaccine confidence. Yet these present and future challenges should be met with firm confidence in the power and promise of vaccination, rooted in the successes of the past 50 years of EPI. It is important that the global health community embrace our shared responsibility and whole-heartedly reaffirm our collective commitment to routine childhood vaccination to deliver on the promise of EPI to provide all people, everywhere the opportunity to live full and healthy lives.

Affiliations

Please see appendix 2 (pp 8–40) for the affiliations for individual authors. See **Online** for appendix 2

Contributors

Please see appendix 2 (pp 40–53) for more detailed information about individual author contributions to the research, divided into the following categories: managing the overall research enterprise; writing the first draft of the manuscript; primary responsibility for applying analytical methods to produce estimates; primary responsibility for seeking, cataloguing, extracting, or cleaning data; designing or coding figures and tables; providing data or critical feedback on data sources; developing methods or computational machinery; providing critical feedback on methods or results; drafting the manuscript or revising it critically for important intellectual content; and managing the estimation or publications process. The lead, corresponding, and senior authors had full access to the data in the study and had final responsibility for the decision to submit for publication.

Declaration of interests

R A Abeldano Zuniga reports consulting fees from the UN International Organization for Migration; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from the University of Helsinki; outside the submitted work. Q E Adnani reports grants or contracts from the Online Library Data Research funds from Universitas Padjadjaran, Bandung, Indonesia, under contract number 2152/UN6.3.1/PT.00/2024 and Scientific

Excellence Research Grant from Universitas Padjadjaran, Bandung, Indonesia, under contract number 908/UN6.3.1/PT.00/2025; outside the submitted work. S Afzal reports grants or contracts from Intellectual contributions and time protection was given by Dean office Institute of Public Health Lahore; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events by the Dean Institute of Public Health Lahore; Support for attending meetings and/or travel from the Dean Institute of Public Health Lahore, Pakistan; participation on a data safety monitoring board or advisory board as a Member Pakistan National Bioethics Committee, Member Institutional Review Board of Fatima Jinnah Medical University, Member Ethical Review Board and Data Monitoring Board Institute of Public Health Lahore Pakistan, In charge Clinical Research Organization King Edward Medical University; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as Member Pakistan Higher Education Commission Research Committee, Member Pakistan Medical and Dental Commission Research and Journals Committee, Member Pakistan Society of Internal Medicine, Member Pakistan Association of Medical Editors, Member Medical Microbiology and Infectious Diseases Society, Fellow of Leads International, Fellow of Faculty of Public Health UK, Fellow of College of Physicians and Surgeons Pakistan; Receipt of equipment from Bergen University Norway for research writing; Other financial or non-financial support from Dean Public Health and Preventive Medicine King Edward Medical University; outside the submitted work. A Aguilera reports grants or contracts from Pfizer Biopharmaceutical Group Andean Cluster (Chile) employee; outside the submitted work. A Amin reports the following pending patents: US20200253891A1; Method of Liver Cancer Treatment with Safranal-Based Formulations; US20200254049A1; Combination Therapy for Cancer; US20200253890A1; Suppression and Inhibition of CDC25B with Safranal-Based Formulations, outside the submitted work. A Bhagavathula reports support for attending meetings and/or travel from the American College of Epidemiology, North Dakota State University, GE Health Care, and NIG to attend meetings and travel in 2024-2025; Leadership or fiduciary role in other board, society, committee or advocacy group, unpaid as a member of the Board of Directors of the American College of Epidemiology, Associate Editor of Jmir Public Health and Surveillance, Associate Editor of Frontiers in Public Health – Digital Health Section, and Associate Editor af Frontiers in Cardiovascular Medicine; outside the submitted work. S Bhaskar reports grants or contracts from Japan Society for the Promotion of Science (JSPS), Japanese Ministry of Education, Culture, Sports, Science and Technology (MEXT), Grant-in-Aid for Scientific Research (KAKENHI; Grant ID: 23KF0126), JSPS and the Australian Academy of Science, JSPS International Fellowship (Grant ID: P23712; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as District Chair, Diversity, Equity, Inclusion & Belonging of Rotary District 9675 (Sydney, Australia), as Chair, Founding Member and Manager of the Global Health & Migration Hub Community, Global Health Hub Germany (Berlin, Germany), as Editorial Board Member of PLOS One, BMC Neurology, Frontiers in Neurology, Frontiers in Stroke, Frontiers in Public Health, Journal of Aging Research, Neurology International, Diagnostics, & BMC Medical Research Methodology, as a member of the College of Reviewers, Canadian Institutes of Health Research (CIHR), Government of Canada, as the Director of Research of World Headache Society (Bengaluru, India), as Expert Adviser/Reviewer of Cariplo Foundation (Milan, Italy), as Visiting Director of National Cerebral and Cardiovascular Center, Department of Neurology, Division of Cerebrovascular Medicine and Neurology, Suita (Osaka, Japan), as Member, Scientific Review Committee of Cardiff University Biobank (Cardiff, UK), as Chair of Rotary Reconciliation Action Plan, and Healthcare and Medical Adviser at Japan Connect (Osaka, Japan); outside the submitted work. D-T Chu reports grants or contracts from the Vietnam National Foundation for Science and Technology Development (NAFOSTED; the Vietnam National University, Hanoi (VNU) VNU International School (as a PI unless otherwise indicated) by the Vietnam National University Hanoi (VNU) for the 2025 research activities of the VNU strong re-search group - the interdisciplinary research group on biomedicine and health (IRGBH; The establishing Decision no. 4013/QĐ-ĐHQGHN on October 24, 2023), by the Vietnam National Foundation for Science and Technology Development (NAFOSTED (grant number 106.02-2019.314), by the Vietnam National University, Hanoi (VNU) under project 'Researching on some clinical, non-clinical, and epidemiological characteristics, and genetic mutation and expression in Vietnamese patients with ovarian cancer' (decision number 776/QĐ-ĐHQGHN), and other internal research grants from VNU International School from 2021 to now; outside the submitted work. J Condo reports grants or contracts from OncoNanoAI: Artificial intelligence to discover the next generation of personalized nanoparticles for triple-negative breast cancer therapy (2025-2027) FCT Grant LISBOA2030-FEDER-00862500-14998; Patents planned, issued or pending from TRPV2 Antagonists. U.S. Application No. US11273152B2 ,Surfactant-based cellulose hydrogel methods and uses thereof, PCT/IB2025/051694, 17/02/2025, Self-immolative micelle, methods and uses thereof, EP25165757, 24/03/2025; outside the submitted work. M Del Riccio reports grants or contracts from Moderna; Support for attending meetings and/or travel from MSD, Sanofi, and Astrazeneca; outside the submitted work. D Dias da Silva reports grants or contracts from Laboratório Associado para a Química Verde-Tecnologias e Processos Limpos (FCT/MECI, Fundação para a Ciência e Tecnologia and Ministério da Educação, Ciência e Inovação) through the project UID/50006-Laboratório Associado para a Química Verde–Tecnologias e Processos Limpos; outside the submitted work. X Ding reports grants or contracts from the American Heart Association (2-year predoctoral fellowship (DOI: 10.58275/AHA.25PRE1373497.pc.gr.227106); quarterly payments made to my institution), outside the submitted work. L M Ebraheim reports support for the present manuscript from the Gates Foundation and Gavi; and royalties or licenses from the Institute for Health Metrics and Evaluation. A Faro reports support for the present manuscript from National Council for Scientific and Technological Development (CNPq, Brazil; Personal grant "Researcher on Productivity at CNPq - Level 2"). N Fullman reports grants or contracts from the Gates Foundation; Other financial or non-financial interests from Gates Ventures (June 2020 to present), outside the submitted work. N Ghith reports grants or contracts from the Technical University of Denmark between 2019-2022 was covered by a grant from Novo Nordisk Foundation (NNF16OC0021856); Support for attending meetings and/or travel from Danish Data Science Institute at the Technical University of Denmark, travel grant in 2023; outside the submitted work. E Haeuser reports support for the present manuscript from the Gates Foundation and Gavi (joint grant #INV-037425 with the Gates Foundation and Gavi, with payments made to the institution). I Ilic reports support for the present manuscript from the Ministry of Science, Technological Development and Innovation of the Republic of Serbia (no. 451-03-137/2025-03/200110). M Ilic reports support for the present manuscript from the Ministry of Science, Technological Development and Innovation of the Republic of Serbia (no. 451-03-47/2023-01/200111). J Jozwiak reports payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from Novartis, ADAMed, and AMGen; outside the submitted work. K Krishan reports other non-financial support from the UGC Centre of Advanced Study, CAS II, awarded to the Department of Anthropology, Panjab University (Chandigarh, India), outside the submitted work. J Liu reports support for the present manuscript from the National Natural Science Foundation (72474005) and Beijing Natural Science Foundation (L222027). E Lytvyak reports grants or contracts from the College of Physicians and Surgeons of Alberta, the Government of Alberta, and Advanz Pharma; Other interests as an employee of the University of Alberta and appointment of Alberta Health Services; outside the submitted work. S Y Ma'aruf reports leadership or fiduciary roles in other board, society, committee, or advocacy group, paid or unpaid as a volunteer Director of Research and Development at InnovateHealth Africa (IHA); outside the submitted work. H R Marateb repots grants or contracts from 2024 LLAV 00083, AGAUR (Agency for Management of University and Research Grants) and UPC Universitat Politècnica de Catalunya; outside the submitted work. M Marks-Hulstram reports grants or contracts from the Swedish Heart-Lung Foundation and Regional Research Foundation Middle Sweden (paid to institution); Royalties or licenses from Liber (intensivvård); payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from the Swedish Association for Anesthesiology and Intensive Care; Support for attending meetings and/or travel from American Physiological Society and the European Society of Intensive Care Medicine; Leadership or

fiduciary role in other board, society, committee or advocacy group, paid or unpaid from the American Physiological Society; outside the submitted work. S Masi reports consulting fees from Servier; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from Servier; Support for attending meetings and/or travel from Servier; participation on a data safety monitoring board or advisory board from Servier; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid from the Italian Society of Internal Medicine; outside the submitted work. R J Maude reports support for the present manuscript from Wellcome Trust [Grant number 220211] as it pro-vides core funding for Mahidol Oxford Tropical Medicine Research and contributes to my salary. I am required by Wellcome to acknowledge this grant in all publications. A-F Mentis reports leadership or fiduciary role in other board, society, committee or advocacy group paid or unpaid as an Editorial Board Member for "Systematic Reviews" journal, for "Annals of Epidemiology" journal, and as Associate Editor for "Translational Psychiatry"; outside the submitted work. S A Meo reports grants or contracts from Researchers Supporting Project, King Saud Universi-ty, Riyadh, Saudi Arabia (RSP-2025 R47); outside the submitted work. L Monasta reports support for the present manuscript from the Italian Ministry of Health (Ricerca Corrente 34/2017), payments made to the Institute for Maternal and Child Health IRCCS Burlo Garofolo. J F Mosser reports support for the present manuscript from the Gates Foundation and Gavi; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from Providence Regional Medical Center (Honorarium for continuing medical education presentation); Support for attending meetings and travel support from the Gates Foundation. S Nomura reports grant support for the present manuscript from Ministry of Education, Culture, Sports, Science and Technology of Japan (24H00663), Precursory Research for Embryonic Science and Technology from the Japan Science and Technology Agency (JPMJPR22R8). B Oancea reports support for the present manuscript from MRID, project PNRR-I8 no 842027778., contract no 760096. A Ortiz reports grants or contracts from Sanofi (IIS-FJD UAM), and grants to Universidad Autonoma de Madrid (UAM) as Director of the Catedra Astrazeneca-UAM of chronic kidney disease and electrolytes; Consulting fees from Astellas, Astrazeneca, Bioporto, Boehringer Ingelheim, Fresenius Medical Care, GSK, Bayer, Sanofi-Genzyme, Lilly, Chiesi, Otsuka, Novo-Nordisk, Sysmex; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from Astellas, Astrazeneca, Bioporto, Boehringer Ingelheim, Fresenius Medical Care, GSK, Bayer, Sanofi-Genzyme, Sobi, Menarini, Lilly, Chiesi, Otsuka, Novo-Nordisk, Sysmex and Vifor Fresenius Medical Care Renal Pharma and Spafarma; Support for attending meetings and/or travel from Astellas, Astrazeneca, Fresenius Medical Care, Boehringer-Ingelheim, Bayer, Sanofi-Genzyme, Chiesi, Sobi, Bayer; participation on a data safety monitoring board or advisory board from Astellas, Astrazeneca, Boehringer-Ingelheim, Fresenius Medical Care, Bayer, Sanofi-Genzyme, Chiesi, Otsuka, Novo Nordisk, Sysmex; Leadership or fiduciary role in other board, society, committee or advocacy group, unpaid from Council ERA. SOMANE; outside the submitted work. S K Panda reports support for the present manuscript from Siksha 'O' Anusandhan (Deemed to be University); Grants or contracts from DST-GOVT. OF ODISHA (Letter No. 3444/ST). R Passera reports participation on a data safety monitoring board or advisory board from dello studio "Consolidation with ADCT-402 (loncastuximab tesirine) after immunochemotherapy: a phase II study in BTKi-treated/ineligible Relapse/Refractory Mantle Cell Lymphoma (MCL) patients" - FIL, Fondazione Italiana Linfomi, Alessandria (Italy); Leadership or fiduciary role in other board, society, committee or advocacy group, unpaid as a Member of the EBMT Statistical Committee, European Society for Blood and Marrow Transplantation, Paris (F) and a Past member 2020-2023 (biostatistician) of the IRB/IEC Comitato Etico AO SS. Antonio e Biagio Alessandria-ASL AL-VC (Italy); outside the submitted work. V C F Pepito reports grants or contracts from Sanofi Consumer Healthcare; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from Zuellig Family Foundation; outside the submitted work. X Qi reports consulting fees from The City University of New York and University of Texas at Austin; outside the submitted work. L F Reyes reports grants or contracts from GSK, MSD, Pfizer; Consulting fees from GSK, MSD, Pfizer; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from GSK, MSD, Pfizer; Support for attending meetings and/or travel from GSK; outside the submitted work. Y L Samodra reports grants or contracts from Taipei Medical University, Taiwan and NSTC – NTU, Taiwan; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as Co-founder of Benang Merah Research Center, Indonesia; Other financial or non-financial interests from idebeasiswa.com as a Mentor; outside the submitted work. F Shahkarami reports grants or contracts from Tehran University of Medical Sciences (TUMS; Department of Internal Medicine); payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from TUMS; Other financial or non-financial interests as a part-time physician (general practitioner) and health consultant; all outside the submitted work. V Sharma reports other financial or non-financial interests from DFSS (MHA)'s research project (DFSS28(1)2019/EMR/6) at Institute of Forensic Science & Criminology, Panjab University, Chandigarh, India, outside the submitted work. L M L R D Silva reports grants or contracts from SPRINT, Sport Physical Activity and Health Research & Innovation Center, Polytechnic of Guarda, 6300-559 Guarda, Portugal; RISE-Health, Faculty of Health Sciences, University of Beira Interior, 6201-506 Covilhã, Portugal; outside the submitted work. J A Singh reports consulting fees from ROMTech, Atheneum, Clearview healthcare partners, American College of Rheumatology, Yale, Hulio, Horizon Pharmaceuticals, DINO-RA, ANI/Exeltis, USA Inc., Frictionless Solutions, Schipher, Crealta/Horizon, Medisys, Fidia, PK Med, Two labs Inc., Adept Field Solutions, Clinical Care options, Putnam associates, Focus forward, Navigant consulting, Spherix, MedIQ, Jupiter Life Science, UBM, Trio Health, Medscape, WebMD, and Practice Point communications; and the National Institutes of Health; payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events from the speaker's bureau of Simply Speaking; Support for attending meetings and/or travel from Simply Speaking; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as a past steering committee member of the OMERACT, an international organization that develops measures for clinical trials and receives arm's length funding from 12 pharmaceutical companies, as Chair of the Veterans Affairs Rheumatology Field Advisory Committee, and as Editor and Director of the UAB Cochrane Musculoskeletal Group Satellite Center on Network Meta-analysis; Stock or stock options in Atai life sciences, Kintara therapeutics, Intelligent Biosolutions, Acumen pharmaceutical, TPT Global Tech, Vaxart pharmaceuticals, Atyu biopharma, Adaptimmune Therapeutics, GeoVax Labs, Pieris Pharmaceuticals, Enzolytics Inc., Seres Therapeutics, Tonix Pharmaceuticals Holding Corp., Aebona Pharmaceuticals, and Charlotte's Web Holdings, Inc. and previously owned stock options in Amarin, Viking and Moderna pharmaceuticals; outside the submitted work. R Tabares-Seisdedos reports grants or contracts from the Valencian Regional Government's Ministry of Education (PROME-TEO/CIPROM/2022/58 and the Spanish Ministry of Science, Innovation and Universities (PID2021-129099OB-I00; The funders were not involved in the design of the manuscript or decision to submit the manuscript for publication, nor will they be involved in any aspect of the study's conduct); outside the submitted work. T Tabuchi reports grants or contracts from Daiichi Sankyo Healthcare, Data Seed Inc., Johnson & Johnson K.K., Workout-Plus; outside the submitted work. J H V Ticoalu reports leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as the co-founder of Benang Merah Research Center, Indonesia; outside the submitted work. S Tromans reports grants or contracts from part of the 2023/4 Adult Psychiatric Morbidity Survey team, collecting epidemiological data on community-based adults living in England (this is a contracted study from NHS Digital, via the Department of Health and Social Care), multiple chapters of the 2023/4 Adult Psychiatric Morbidity Survey report, Co-lead on a study from Jazz Pharmaceuticals related to reviewing the impact of medicinal cannabis on patients with the epilepsy syndromes Lennox-Gastaut syndrome and Dravet syndrome, lead on a study from the National Institute for Health and Care Research related to reviewing a national training programme for health and social care professionals relating to learning disability and autism, co-applicant on studies funded by the National Institute for

Health and Care Research related to (1) medicine support interventions and strategies for people with learning disabilities and (2) Identification, recording, and reasonable adjustments for people with a learning disability and autistic people in NHS electronic clinical record systems, co-lead on a study investigating multiple antipsychotic prescribing in adults under the care of specialist learning disability services (funded by the Baily Thomas Charitable Fund); all payments made to institutions. Support for attending meetings and/or travel from the Royal College of Psychiatrists for accommodation and travel to conference events due to my academic secretary role in the faculty of the Psychiatry of Intellectual Disability and conference fees for Royal College of Psychiatrists events; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as Academic Secretary for the Neurodevelopmental Psychiatry Special Interest Group and Psychiatry of Intellectual Disability Faculty at the Royal College of Psychiatrists; Editorial Board Member for Progress in Neurology and Psychiatry, Advances in Mental Health and Intellectual Disability, Advances in Autism, BMC Psychiatry, and BJPsych Open. Editor of Psychiatry of Intellectual Disability Across Cultures (Oxford University Press), outside the submitted role. E Upadhyay reports patents planned, issued or pending; A system and method of reusable filters for anti-pollution mask, A system and method for electricity generation through crop stubble by using microbial fuel cells, A system for disposed personal protection equipment (PPE) into biofuel through pyrolysis and method, A novel herbal pharmaceutical aid for formulation of gel and method thereof, Herbal drug formulation for treating lung tissue degenerated by particulate matter exposure, a method to transform cow dung into the wall paint by using natural materials and composition thereof, Biodegradable packaging composition and method of preparation thereof, Eco-friendly bio-shoe polish from banana and turmeric, Honey-based polyherbal syrup composition to treat air pollution-induced inflammation and preparation method thereof, Process for preparing a caffeine free, antioxidant and nutrient rich beverage; Leadership or fiduciary role in other board, society, committee or advocacy group, paid or unpaid as Executive Council Member, Indian Meteorological Society, Jaipur Chapter (India) and as Member Secretary-DSTPURSE Program; outside the submitted work. J Ward reports support for the present manuscript from NIHR Clinical Lecturer 2022 – 2025. P Willeit reports consulting fees from Novartis Pharmaceuticals; outside the submitted work. J Wu reports grants or contracts from the National Heart, Lung, and Blood Institute (R38HL167238) and acknowledges prior funding from the American Society of Hematology, Hematology Opportunities for the Next Generation of Research Scientists (HONORS) Award; outside the submitted work. Y Yasufuku reports grants or contracts from Shionogi & Co; outside the submitted work. G Zamagni reports support for the present manuscript from the Italian Ministry of Health (Ricerca Corrente 34/2017), payments made to the Institute for Maternal and Child Health IRCCS Burlo Garofolo. A B Zemariam reports support for the present manuscript from funding provided by the Gates Foundation and Gavi. The funding agency has no role in data collection and interpretation.

Data sharing

This study follows the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER). To download the estimates produced in these analyses, please visit the Global Health Data Exchange website at https://ghdx.healthdata.org/record/ihme-data/gbd-2023-vaccination-coverage-1980-2030. Data sources are also listed by location and institution in appendix 1 (pp 15–145).

Acknowledgments

This study was funded by the Bill & Melinda Gates Foundation and Gavi, the Vaccine Alliance.

Editorial note: The Lancet Group takes a neutral position with respect to territorial claims in published maps and institutional affiliations.
