Research Paper

Traditional Versus Heterodox Motives for Academic Patenting: Evidence from the Netherlands

ISABEL MARIA BODAS FREITAS* & ALESSANDRO NUVOLARI**

**Grenoble Ecole de Management, France & DISPEA, Politecnico di Torino, Torino, Italy, **LEM Sant'Anna School of Advanced Studies, Pisa, Italy*

ABSTRACT This paper examines what motivates university researchers to patent the results of collaborative research with business firms. We provide evidence of the existence of a motivational academic patenting space comprising (i) an industry-driven domain related to traditional-market motives (protection of inventions that will be commercialized); (ii) a university-driven domain driven by various (“heterodox”) motives related mostly to signalling specific research competences and (iii) a “hybrid” publicly driven domain related to projects aligned to the research agendas of public sponsors. These three types of motivations reflect the connections between academic patenting and different types of innovation, and the roles of industry partners in proposing, financing and performing specific research projects. We use data from 16 in depth case studies of innovations developed by Dutch universities to provide preliminary empirical evidence of this typology of motivational spaces for patenting university knowledge.

KEY WORDS: Patents, motivations, collaborations, university–industry interaction, signalling

JEL CODES: O34, O31, O38

1. Introduction

The increasing number of studies on academic patenting reflects a growing recognition of the critical role of universities for economic development, and the fact that the financing of university research relies heavily on the commercialization of research results.¹ The 1980s’

¹In line with previous studies, in this paper, we use the term ‘university patenting’ to refer to university-owned patents, and academic patenting to indicate the broader set of both university-owned and university-invented patents (Lissoni *et al.*, 2008).

US Bayh–Dole Act sets new rules for the ownership of university research results and marked the emergence of a new context for academic patenting. Revisions to the regulation of intellectual property rights (IPR) on university research results are taking place in many other OECD countries. There is a general trend towards reinforcement of the incentives for university patenting, with the aim of facilitating knowledge transfer (see OECD, 2003, for an influential report that advocated policy changes).

Patents are a form of exclusionary rights granting temporary monopoly on the commercial exploitation of inventions. The traditional motivation for a patent application is the intention to appropriate some economic return from an invention, either through its direct commercializing or by licensing it to a third party. However, some scholars have suggested that other benefits, such as increasing bargaining power in technology agreements, signalling specific research capabilities, gaining access to research networks or enhancing reputation, may be influencing firms' decisions to patent (Hall & Ziedonis, 2001; Bureth *et al.*, 2005; Penin, 2005; Fontana *et al.*, 2006).

These various reasons may apply also to academic patenting and it is useful also to make a distinction between traditional and "heterodox" motivations in these cases (MacLeod, 1988). Traditional motivations are related to the expectation of appropriating some economic return from the legal protection of an invention provided by a patent. 'Heterodox' motivations include exploitation of a patent for purposes not directly linked to the protection of an invention: for example, to enhance reputation, signal competences, etc.²

Most policy discussion on academic patenting so far revolves around the effects of patent protection, and tends to ignore the specific motivations underlying the academic researcher's decision to patent. If academic researchers patent for other reasons than protecting the economic returns from their inventions, then universities patenting policies may be misguided and need to be realigned (Metcalfe, 1995).

Academic patenting seems to result from the analysis of the direct financial benefits generated by the patent as well as the indirect benefits such as effect on the individual researcher's scientific reputation or bargaining power inside the university (Owen-Smith & Powell, 2001; Baldini *et al.*, 2007; Penin, 2010; D'Este & Perkman, 2011). Göktepe-Hulten & Maghagaonkar (2010) examine the importance of university researchers' reputational versus pecuniary motivations to explain patenting and disclosure behaviour, and find that heterodox motivations are only important to explaining patenting by university researchers with no experience of collaboration with industry. However, we do not know whether or not different patenting motivations are associated with the specificities of the innovative process, in particular, the organizational format and technological objectives. The characteristics of the innovation development process may influence the patenting decision, especially under collaborative arrangements between industry and university (Aghion & Tirole, 1994; Colyvas *et al.*, 2002; Verspagen, 2006).

² The distinction between traditional and heterodox motivations for patenting was introduced by MacLeod (1988) in her historical study of the English patent system. MacLeod noted that many patents granted in the period 1660–1800 were aimed at being used as advertising devices or, in the case of amateur, 'gentlemen' inventors, for public recognition of their scientific and technological efforts, rather than for the direct economic exploitation of a specific invention (MacLeod, 1988, pp. 75–96).

This study constitutes a preliminary exploration of academic patenting motivations in the context of collaborative projects with different organizational and technological characteristics. We explore how traditional and heterodox patenting motives relate to different types of innovation (“embryonic” vs. “ready-to-use”), different forms of financing and organizing research, and different patent ownership. On the basis of 16 case studies on university–industry collaborative projects in the Netherlands we propose and provide evidence of the existence of a three-domain motivational space for academic patenting comprising: (i) an industry-driven domain related to traditional-market motives (protection of inventions that will be commercialized); (ii) a university-driven domain related to heterodox motives (mostly related to the signalling of specific research competences); and (iii) a “hybrid” publicly driven domain that includes projects aligned to the research agendas of public research sponsors. This three-domain motivational space reflects the different connections between incentives to patent and types of innovation, and the role of industry partners in proposing, financing and performing specific research projects.

The paper is organized as follows. Section 2 reviews the motives for academic patenting; Section 3 proposes the conceptual framework for university patenting and Section 4 presents the data used. Section 5 discusses the characteristics of the projects in each of the three motivational spaces, and the co-occurrence of patenting motivations, innovation characteristics and involvement of an industry partner. Section 6 concludes with some implications for policy.

2. Motives for Patenting

A patent is a legal tool that grants an inventor the temporary exclusive rights to produce, use or market a specific invention. Traditionally, it was believed that in the absence of patent protection, competitors would immediately copy the invention, at almost no cost, giving the original inventor little hope of recouping the investment in the inventive activity (Verspagen, 2006). Empirical research on patenting motives, however, reveals a more complex picture. First, in most industries (notable exceptions being chemicals and pharmaceuticals) first-mover advantages and secrecy are considered to be far more effective methods than patents for protecting innovations (Cohen *et al.*, 2000). Second, patents are used frequently by firms for other strategic objectives than protection of innovation. For example, the Carnegie–Mellon survey revealed that alongside the usual motives of preventing copying and generating revenue through licensing, patents are used to block rival patents, to negotiate with other companies to prevent infringement suits, to enhance reputation and to measure the performance of research and development (R&D) departments (Cohen *et al.*, 2000). Other studies show that patents can combine the traditional role of protection and exclusion with the heterodox role of a negotiation and cooperation instrument (Hall & Ziedonis, 2001; Bureth *et al.*, 2005; Bureth & Penin, 2007). In other words, patents simultaneously act to promote collaboration and protection. Bureth & Penin (2007) argue that patents can be understood as architectural elements of complex modular products because they protect against competition (within each module, they act as tools of exclusion and protection) and foster cooperation (across modules). This heterodox role of patents is more frequent in the area of life sciences (Bureth *et al.*, 2005).

In the case of academic patents, the situation is more complex. As Verspagen (2006) points out, university research can be regarded as a prime example of a system of

patronage, in which the development of new knowledge is supported directly by public funding. Therefore, university research is knowledge created by an incentive system, which, from a historical point of view, has emerged as an *alternative to the patent system*. In this perspective, the rationale underlying current policy measures that encourage the patenting of university research findings appears to be ambiguous because these procedures create incentives for investment in the production of new knowledge by actors whose research efforts are supported by public funds (Jensen *et al.*, 2003; Verspagen, 2006). Not surprisingly, much of the research on academic patenting focuses on the effects of the co-existence of these two incentive systems—public funding and patents—on the behaviour of academic researchers. Several studies examine issues such as possible delays in the publication of research results, diversion of effort from basic, fundamental research to more “applied” work, etc. (Geuna & Nesta, 2006; Manjarrés-Henríquez *et al.*, 2008; Welsh *et al.*, 2008; Penin, 2010). Concern about the possible detrimental effects of patenting university research results came to a head between 1910 and 1939 when some US universities began to take patents on some of their discoveries (see Metlay, 2006 for an interesting study of these early discussion on the rationale for university patenting).

Empirical research on academic patents tends to focus on traditional reasons for patenting (e.g. Colyvas *et al.*, 2002; Jensen & Thursby, 2004). However, as already mentioned, research on corporate patenting reveals that patenting can have many different motives. This leads to questions about whether the patterns of motivations are similar for university patenting and whether patenting occurs for other reasons than protection. Such an investigation is important to assess the potential effects of recent public policy measures designed to encourage university patenting.

Few studies examine heterodox and traditional motivations for academic patenting. In the US, university patenting and disclosure behaviours seem to be affected by the expectation of personal pecuniary rewards (e.g. Owen-Smith & Powell, 2001; Friedman & Silberman, 2003). Studies using European data suggest that heterodox patenting motives, such as access to research funds and resources, and reputation are more important (e.g. Baldini *et al.*, 2007). In particular, Göktepe-Hulten & Maghagaonkar (2010), using survey data, examine the importance of reputational and pecuniary reasons for patenting and disclosure behaviours among university researchers—with and without industry-collaborative experience. Their results suggest that heterodox motivations are only important for explaining patenting by university researchers with no experience of collaboration with industry, and that pecuniary motivations are negatively associated with disclosure and patenting by university researchers with industry cooperative experience. Given the nature of survey data, Göktepe-Hulten & Maghagaonkar (2010) are unable to identify how these motivations are associated with different types of innovative processes, and do not take account of the organizational form or technological objective of collaborative projects with industry.

However, the characteristics of the invention and its development process seem to influence the motivations to patent, especially under collaborative arrangements between industry and university (Colyvas *et al.*, 2002; Aghion & Tirole, 1994; Verspagen, 2006). Aghion & Tirole (1994) argue that the allocation of IPR in university–industry collaborations is related to both the nature of the innovation and the characteristics of the research team.

The present study provides a preliminary exploration of academic patenting motivations, and especially heterodox and traditional incentives, in projects with different organizational

and technological characteristics conducted in collaboration with industry. Section 3 proposes an interpretative framework for understanding the incentives for universities and academic researchers to apply for patents on research findings.

3. Motivational Spaces for Patenting University Research Results

We start by considering that the motivations for university patenting are an outcome of the context in which the new knowledge is generated. In other words, patenting of innovations developed in collaboration with industry and developed autonomously by academic researchers may have different intrinsic motivations. The reasons for patenting may vary across different phases of development of an innovation (i.e. whether the innovation is at an “embryonic” or “ready-to-use” stage). Also, university or industry ownership of the IPR of an innovation seems to depend on the context of its development and the level of development and applicability of the knowledge (Colyvas *et al.*, 2002; Metlay, 2006; Verspagen, 2006).

Embryonic proof-of-concept as opposed to ready-to-use innovation is more likely to be protected by a patent for heterodox reasons such as signalling and attracting partners that could provide financial support for further development and refinement of the invention (Colyvas *et al.*, 2002; Bureth & Penin, 2007). Innovations that replace existing technologies and open up new market opportunities are more likely to be patented for heterodox motivations (Metlay, 2006). In both cases, although part of the reason for patenting may be traditional protection, it is important for the inventor to attract new research partners and resources to allow further development of the innovation (Geroski, 2000; Metcalfe, 2005).

Embryonic proof-of-concept and ready-to-use innovations tend to be developed in different organizational environments, and have different objectives and arrangements for eventual ownership. Proof-of-concept inventions developed by universities are typically generated in “curiosity-driven” type of research contexts, supported by public funds and, for these reasons, will be less suitable for immediate industrial application. University-owned patents tend to refer more often to embryonic innovation based on public funds than private patents (Colyvas *et al.*, 2002; Azagra-Caro *et al.*, 2006).

Innovations developed in contexts of limited interactions with industrial firms, or autonomously by academic teams, are more likely to be patented for heterodox motivations than innovations developed in direct cooperation with firms (Göktepe-Hulten & Mahagaonkar, 2010). In the former case, patenting provides a way for academic researchers to signal to public research sponsors, the quality and potential for industrial application of their ongoing research and to attract private funds and partners for future innovation development projects (Geuna & Nesta, 2006; Czarnitzki *et al.*, 2011). Heterodox motivations for patenting may be less important in contexts of strong interaction with industrial firms, especially if these firms participate actively in the design and performance of the research collaboration. Hence, university researchers with experience of collaboration and interest of continued cooperation with industry may mimicking the traditional market-led patenting motivations of their industrial partners who are more likely to expect and understand the market potential of an innovation (Slaughter *et al.*, 2002).

Based on these considerations, we suggest a typology of university–industry interaction comprising three broad domains of motivations for academic patenting based on the type of innovation and the organizational and financial contexts of the research project (see Figure 1). Figure 1 considers a research project as spanning three dimensions: (i) the degree of involvement of industrial partners; (ii) nature of the innovation and (iii) type of motivations for

Figure 1. An interpretative framework for university patenting. Note: Elaboration by the authors based on the review of the literature.

the decision to patent. This leads to the identification of three types of research projects: *industry driven* where patenting is mainly for traditional motives; *university driven* where patenting is likely to be driven by heterodox motives and *publicly driven* “hybrid” type projects where patenting combines traditional and heterodox motives.

Figure 2 depicts the characteristics of each motivational space for university patenting behaviour. The *industry driven* refers to collaborative R&D projects where a firm that is familiar with the research competencies of the university based on previous collaborations

Figure 2. The three-pronged motivational space of university patenting. Note: Elaboration by the authors.

or professional contacts proposes a collaborative project or asks for help in resolving a technological problem. These projects are often high on the firm's research agenda and its in-house research groups are likely to contribute directly. Depending on the type of research, the university researchers may perform their research at the firm's facilities in order to access specific equipment and facilities. The firm tends to finance most of the research costs. These types of projects may be aimed at improvements to existing technological applications, prototypes or product commercialization. Patents are typically aimed at protection and, in most cases, are owned by the firm. University researchers working in close collaboration with industry researchers tend to reproduce the patenting motivations of their industry partner. Continuation of the project and direction of the research may depend on the firm's interest in supporting it by providing access to equipment, testing facilities and/or funds and the possibilities for the firm to appropriate some benefits from the collaboration.

University-driven research tends to be conducted in an academic or government institute and be mostly "curiosity driven" although it may be the result of some contract research and may lead to a by-product innovation. Innovation is usually developed in research projects performed almost exclusively by university researchers; if a firm is involved this usually consists of provision of material, equipment or technical feedback. *University-driven* projects are usually financed by public research grants or exploit university resources such as masters and research students. Patenting of research outcomes (usually proofs of concept or substitute for existing technologies) tends to be driven by heterodox motives, including signalling of research competences, access to research funds and opportunities to continue the research agenda.

Publicly driven research refers to projects related to technical proofs of concept and prototypes aligned to the research agendas of the public research sponsors. These projects rely on a mix of private and public fundings, and involve different forms of organization of research activities between the university and the firm. They tend to be related to innovations to substitute for existing technologies. Patenting the results of these projects is led by traditional as well as heterodox motives.

4. Data and Methodology

The empirical evidence used in this paper relates to academic patenting in the Netherlands. *Prima facie*, the Dutch case is particularly interesting. The Netherlands has the highest shares of business-owned patents based on university knowledge and business patents with university inventors (Verspagen, 2006). Recent estimates suggest that 4.3% of Dutch patenting with the European Patent Office (EPO) relates to academic inventors (similar to the levels in other European countries such as France and Italy) and that on 1% of Dutch EPO patents, the assignee is a Dutch university (the corresponding percentages for France and Italy are lower) (Baselli & Pellicciari, 2007; Lissoni *et al.*, 2008).

The Dutch university system historically has enjoyed a high level of autonomy from central government. Funding of Dutch universities comes from three main streams. The first is public funding which is allocated according to numbers of students and fields of study. The second stream is represented by funding for research, allocated through competitive grants awarded by the research councils (the most important is the NWO, Nederlandse Organisatie voor Wetenschappelijk Onderzoek). The third funding source is contract

research involving both business firms and public partners. The share of this third stream is about 30% at the national level (VNSU, 2012).

Technology Transfer Offices (TTOs) began to be established in Dutch universities during the 1980s and early 1990s. In the European context, Dutch TTOs provide effective IPR consulting services (OECD, 2003; Verspagen, 2004). The Dutch university system does not acknowledge the so-called “professor’s privilege”, which means that Dutch universities and public research organizations can assume ownership of the inventions made by their researchers. The decision to patent, therefore, is not confined to individual researchers, but is the outcome of discussion or negotiation with the TTO. Although the legislation has not changed, the Dutch government has been encouraging more patenting of the results of academic research (Minister of Economic Affairs, 2003; Verspagen, 2004). This can be seen as part of a broader shift in Dutch innovation policy, which increasingly is trying to link public research funding to industrial applications that provide direct contributions to social welfare.

We collected novel project/collaboration level data from 30 case studies of university–industry collaboration, to investigate the dynamics of the organizational and technological structure of the cooperative projects. The unit of analysis is the piece of knowledge developed or co-developed at the university and transferred to the firm, regardless of whether it is used or commercialized.³ We focused on completed projects where the knowledge developed was transferred to the firm, independently of whether the firm has recognized its value or decided to use it. By focusing only on completed projects we were able to collect data covering both project origins and achieved outcomes. However, it may be that this choice of completed collaborative projects biases the sample towards successful cases, although we found a mix of performance.⁴ Also, we focus on patenting motivations rather than performance *per se*.

We used several strategies to identify our cases, including interviews with the chairs of research departments in the faculties of mechanical engineering, biotechnology, chemistry, applied physics and electrical engineering in two technical universities in the Netherlands (Eindhoven and Delft); library searches for PhD theses completed in the previous five years; records of research grants awarded by national research councils; interviews with directors of university TTOs and identification of professors with large numbers of industrial patents.

Since this work is exploratory we are interested in variety in our sample of cases. The 30 cases demonstrate variety in forms of funding, scientific disciplines, and origin and development of inventions (university-driven research; firms proposing project ideas to the university; results of on-going collaboration).

To enable codification and statistical comparison of the cases, we developed a standardized protocol for collecting data from university researchers and industry researchers and managers participating in the specific projects. This protocol included over

³ Among the 30 cases, we found three levels of knowledge transfer: knowledge transferred but not valued or exploited by the firm; knowledge that was absorbed by the firm which regarded it as valuable but did not exploit it further and knowledge that was exploited in further research, product development, process improvements or commercialization of new products.

⁴ In 2 of the 30 cases, the collaborative project did not achieve the scientific or technological objectives defined at the start of the project; in four cases the outcomes were beyond what was expected; in 17 cases, projects led to commercialization efforts or plans for commercialization of new products. The universities evaluated 26 projects as completely positive; the firms were more critical and reported complete satisfaction with outcomes in only 21 cases.

200 questions focusing on the processes of knowledge development and transfer between universities and firms, which includes (Bozeman, 2000; Bercovitz & Feldman, 2006) (i) characteristics of the innovation; (ii) identification of project origins; (iii) design and performance of the R&D project; (iv) degree and forms of knowledge transfer between university and firm; (v) impact of the knowledge transfer process and (vi) main characteristics of university researchers and participating firms.⁵ Collection of data in each case involved between two and five interviews with the university and industry partners.

We identified 16 cases from the original 30 case studies that involved academic patent applications, that is, applications based on a decision to patent by the university researcher. Our sample of 16 cases includes 4 cases related mainly to Mechanical Engineering, 3 in Biology and Medicine, 3 in Applied Physics, 3 in Electrical Engineering, 2 in Chemistry and Chemical Engineering and 1 in Bio-mechanics. In nine cases, the idea for a collaborative project came from the university researchers; three of these were former industry researchers and two were part-time professors. Five cases were mainly proposed by firms; the others were continuations of previous or on-going collaborative research. In relation to funding, two cases were supported by public subsidies, five were fully financed by the firms, and the remaining nine were funded by a mix of public and private sources.⁶

Table 1 provides information on the technology, disciplinary affiliation, type of funding for development, relative size of research team in yearly full-time equivalents, project timing and timing of patent application and its ownership.

In relation to timing of patent applications, in 10 cases, projects were built on previous patents; 6 were patents on university knowledge (two owned by the firm). In 15 cases, patents were awarded during or towards the end of the project; in only 2 cases was the patent university owned.

In four cases, the project led to the creation of a spin-off firm, one of which was a start-up. In three cases, the spin-off was the form used to implement the research project because it facilitated access to research sponsorship and collaborative agreements.

The categorization of innovations into embryonic or ready-to-use innovations is difficult because the meaning of these terms differs across disciplinary fields and industrial contexts. To address this, we create two objective dichotomous variables that can be used as proxies: "substitute versus complement to existing technologies" and "degree of technology development" (Geroski, 2000; Metcalfe, 2005). The variable "substitute versus complement to existing technologies" defined in terms of knowledge application rather than knowledge characteristics, considers whether the existing innovation complements or substitutes the existing technology (Metcalfe, 2005). The variable "degree of technology development", reflects the different development phases leading to new technology and knowledge at the end of the research project, and considers whether the project resulted in proof of concept rather than a developed crafted technology or industrial application. These variables are based on information reported by interviewees on the characteristics of the innovation, complemented in some cases by secondary sources.

Innovations that are complementary to existing technologies represent less complex ways to improve technology efficiency and market performance. Innovations that represent

⁵ The protocol consists of mainly open questions and some yes/no questions.

⁶ Eleven cases relate to the University of Eindhoven, three to the University of Leiden and two to Delft University.

Table 1. General information on the 16 projects that involved the publication of patents.

Technology	Discipline	Funding	Size of research team	Starting	Time	Previous patents	Previous patents based on University knowledge	Previous University owned patents	Number of output patents	Output University owned patents	Spin off
Flywheel	Control system, mechanical engineering	R&D sponsoring of 60%	3	1997	5				2		End
Guide-wire mounted sensor to measure pressure and temperature in the coronary artery	Biomechanics and tissue engineering, biomedical engineering	Mainly R&D sponsoring	2	2002	4	Yes			1		
Supervisory control of wafer scanners	Systems engineering, mechanical engineering and mathematics and computer science	Mainly private	1	2002	3				7		
Rare earth activated-(oxy) nitride materials for LED applications	Materials and interface chemistry, chemical engineering and chemistry	Half private half public	1	2001	2 + 3	Yes	Yes		2		
Manufacturing method of photovoltaic foil	Plasma and material processing, applied physics	1st part R&D sponsoring; 2nd, 50% private; 3rd 100% private	5 to 8	1998	11	Yes	Yes	Yes	12		
Fully integrated in-line solar cell machine for high rate deposition of silicon nitride	Plasma and material processing, applied physics	100% private	0.2	2002	2	Yes	Yes	Yes	4

substitutes for existing technologies may involve deeper organizational changes to establish a market (Geroski, 2000; Metcalfe, 2005). Therefore, the motivations for patenting these two types of innovations can be expected to be different (see Section 3). This classification allows us to control for disciplinary differences in the innovation development time frame. Hence, these dichotomous variables capture the degree of substitution/complementarity with existing technologies and degree of technology development, which allows comparison across disciplinary fields and industrial contexts.

Among the 16 cases, 12 focus on knowledge related to technologies that are substitutes for the existing ones. Eight cases led mainly to development of proofs of concept of new technologies and eight cases resulted in crafted prototypes and industrial applications.

We use data collected from both university and industry partners to characterize the innovation development process, the innovation and the forms of financing and organizing the research project. We use information provided by university researchers participating in the 16 cases to reconstruct their motivations for applying for patents on pieces of new knowledge generated during the project. We coded the motivations reported by university researchers into seven different motivations, traditional (three) and heterodox (four). In this study we examine motivations in the context of collaboration, which involves teams of researchers. Consequently, we include (all) the motivations reported by the university researchers involved in the innovation development project rather focusing on the motivations of individuals, departments or universities.

5. Motivations for Academic Patenting

5.1 Motivations for Patenting, Types of Innovation, Research Funding and Patent Ownership

We codified the motivations reported by university researchers into traditional market-related and heterodox-signalling motivations. The traditional-market patenting motivations identified are “Securing the benefits from future product development”, “Guaranteed ownership of IPR on new products” and “Return on R&D investment from sale of innovation”. Securing the benefits from future product development refers mainly a pre-emptive claim by the patent owner on the rights over future developments based on innovation. Guaranteed ownership of IPR on new products’ allows the patent owner to commercialize the product without others being able to claim right or inappropriate use of their IPR. Selling the information to obtain a return on R&D investment is directed mainly to obtaining a (partial) return on earlier investment in research when the firm is no longer interested in directly applying the innovation.

The heterodox-signalling motivations identified are “Publication of valuable research results”, “Signalling to potential (industry) research partners”, “Attracting venture capital” and “Attracting research funds”. The first refers to the diffusion of valuable research results and building scientific and industrial reputation. Signalling to potential partners is aimed at attracting future collaboration partners demonstrating technical capability and assuring exclusivity of research results. Attracting research funds is aimed at attracting (mainly public) funds for new research projects along similar lines. Attracting venture capital is mainly to fund the cash flow of spin-offs in addition to R&D.

Table 2. Frequency and complementarity among motivations for patenting.

	Traditional motives			Heterodox motives					Any heterodox motive

Total	11	11	2	15	8	8	7	5	10

Notes: Spearman's correlation coefficients used to assess complementarity. ** $p < 0.01$, * $p < 0.05$.

Table 2 provides information on the frequency of the motivations identified by researchers involved in the case projects, and on the degree of complementarity/substitution among motivations. In all cases, one of the motivations for patenting was in the traditional category. In 10 cases, at least one motivation was heterodox. Securing the benefits from future product development and Guaranteed ownership of IPR on new products' were cited in 11 cases. Signalling to research partners and Attracting R&D sponsorships were the motivation in eight cases and Publication of valuable research was the motivation in seven cases.

Heterodox and traditional patenting motivations, therefore, are not mutually exclusive, which is in line with research on motivations for industrial patenting (Bureth *et al.*, 2005; Bureth & Penin, 2007). Only the traditional motivation of Guaranteed ownership of IPR on new products seems to be a substitute for heterodox motivations (significant and negative correlation coefficient). It is somewhat surprising that traditional motives (compared with heterodox motives) do not seem to complement each other (no significant correlations were found).

Table 3 provides information on frequency and linear association between the motivations for patenting and the characteristics of innovation in relation to the degree of technological development and substitution among existing technologies.

Eight projects focused on development of proofs of concept, and patenting in all these cases has heterodox motives. Eleven cases were substitutes for rather than complements to existing technologies; heterodox motivations were reported in nine cases. Heterodox motivations for patenting seem more likely to be related to proofs of concept and innovations that are substitutes for existing technologies.⁷ This suggests that the more embryonic the knowledge produced by the project the more likely the motivations for patenting will be heterodox.

The traditional motive of securing the benefits from future product development is reported in seven cases focusing on development of proof of concept, and nine projects related to the development of substitutes for existing technologies. Hence, there does not seem to be a link between traditional market-related motivations for patenting and the characteristics of the innovation. Still, obtaining a return on R&D investment seems to be related mainly to innovations complementing rather than substituting for existing technologies. An innovation that is considered to be readily marketable is one for which there is an already existing supply and demand market, that is, an innovation that complements an existing technology (Geroski, 2000; Metcalfe, 2005).

Table 4 provides information on the frequency and association between the motivations for patenting and the role of the project's industrial partners.

In 11 cases, the industry partner participated in the design of the research. In 10 of these cases, the motivations for patenting were traditional, and 7 there were heterodox motivations. In research projects where the industry partner actively participated in the research activity (seven cases), traditional patenting motivations are slightly more frequent. In these cases the traditional patenting motivation was guaranteeing IPR on new products. In only three of these seven cases were heterodox-signalling motives reported as reasons

⁷ Heterodox motives for patenting seem particularly frequent in research projects in Biology and Medicine.

for patenting. Since industry partners invest resources and time in collaborative projects, and interact with the university researchers, motivations related to the appropriation of market value, which tend to be more aligned to achieving immediate industrial applications, are more frequent. In five cases, the industry partner financed a large part of the research activity; in none of these cases was access to venture capital identified as a motivation for patenting, and heterodox motivations were reported in only two cases. In four of these five cases, the motives were traditional. Thus, the evidence suggests that the higher the involvement of the industry partner in the research project the less likely that the motives for patenting will be heterodox.

Finally, we examined the frequency and linear association between patenting motivations and the existence of previous patents including all previous patents, previous patents based only on university developed knowledge and previous university-owned patents. The impulse to patent seems not to depend on the existence of a previous patent (i.e. of a patent granted prior to the emergence of the new research results). Only the motivation of securing the benefits from future product development was found to be slightly more frequent in collaborative research to develop previously existing patents, independent of the type of their patent ownership.

We find a weak association between patenting motivations and ownership of patents issued during or towards the end of a research project. In the case of research results belonging to the university (leading to a university-owned patent), patenting seems slightly more likely to be motivated by the heterodox objectives of publishing valuable research results and building scientific and industrial reputation; traditional-market patenting motivations seem less important in the case of university patenting. The motivations for academic patenting, therefore, may depend on whether the university retains (or not) the property rights to the results of a collaborative research project.⁸

5.2 Typology of University–Industry Collaborative Projects and Motivations for Academic Patenting

To explore the applicability of the taxonomy of motivational spaces to patenting of university knowledge, we split the cases into three groups—cases where no heterodox motivations were found, cases with at least three heterodox motivations and cases with one or two heterodox motives—and analyzed similarities and differences within and across groups.

First, we analyze the characteristics of the six cases where patenting was not led by heterodox motives. Five of the projects were proposed to the university by firms and fitted with the firms' research agendas. None of the projects resulted only in proof of concept; all resulted in improvements and refinements to existing technologies. In three cases, the projects led to commercialization of a new product. In two cases, the innovation was a substitute for an existing technology. Two cases were in the area of Mechanical Engineering, two were in Electrical Engineering and two were in Applied Physics.

Four of the six cases were financed mainly by the firms, which participated directly in the research. In three cases university researchers joined the firms' research teams. A fifth

⁸ No significant relationship was found between patenting motivations and the type of patent (domestic/international) issued.

case, which was financed mainly by public research sponsors and conducted at the university, was initiated and led by a part-time professor who was employed by the industry firm. The sixth case was a university department that had been working on an industry-related problem for over a decade before the methodology used to address the problem resulted in a spin-off. When the product was developed and patented the university department closed down. This group of cases fits the industry-driven domain of motivations for patenting university-developed knowledge. Strong involvement and the interest of university researchers in industry's activities seems to reproduce the market-related patenting motivations traditionally applying to their industry counterparts.

The next six cases involve at least three heterodox motives for patenting. All relate to proof-of-concept outcomes that complement existing technologies. Five of the projects were financed by public sponsorship or university funds. These projects were developed mainly at the university. Industry partners were not directly involved in performing the research, although they provided material, equipment, testing facilities and feedback. Three cases were in the areas of Biology and Medicine, the remaining three respectively were in Chemistry, Mechanical Engineering and Electrical Engineering. This group of cases belongs to the university-driven domain patenting motivations.

In the last four cases, patenting motives were both traditional and heterodox. Three refer to development of substitutes for existing technologies; two refer to proofs of concept (one project was discontinued as soon as the firm obtained proof-of-concept knowledge). The projects were in the four disciplinary areas of: Mechanical Engineering, Medicine, Chemical Engineering and Applied Physics. This "intermediate" group overlaps with the previous two groups. In one case, before engaging in the collaborative project, the firm had patented university knowledge, which, the university permitted to secure industry collaboration (the university also reported some of the firm's pre-emptive traditional-market motives). In another case, a university-owned patent, patented for heterodox motivations, existed prior to the collaborative research project, which was aimed at developing knowledge related to the existing patent. The firm patented the emerging results while the collaborative project was still running. The motivations reported include the heterodox motives of attracting other industry research partners and accessing public funds, as well as some traditional-market reasons. The remaining two projects were financed mainly by public research funds and patenting was motivated by diffusion of research results and attracting more research funds.

This analytical and descriptive exercise of clustering cases according to the presence of heterodox motives for patenting provides some insights into the multivariate nature of the motivational spaces encompassing patenting decision. It discusses how and why research projects that differ according to the role of the industry partner in proposing and financing the project and participating in the research tend to produce different types of innovations and result in different motivations for patenting. The empirical evidence supports the taxonomy of motivational spaces for patenting derived in Section 3.

5.3 Three Typical Cases

In this section, we summarize three projects that can be considered typical of the industry-driven, university-driven or public-driven domains according to the patenting motivations identified by the researchers involved in the projects.

Industry-driven collaborative project. The invention was an improved control system for complex manufacturing machines (e.g. wafer scanners). The invention process involved collaboration between the Department of Mechanical Engineering in a technical university and a leading Dutch manufacturer of integrated circuits. The motivation for the project was the company's need to improve the efficiency of its wafer scanners. Aware of these technical concerns, the university project leader proposed the setting up an "applied" PhD research project with the aim of designing more efficient control system software. Although the innovation project was formally proposed by the university partner, through previous contacts the company had expressed its need for the innovation. The PhD research project was initiated (the PhD researcher's salary was covered by the company) and proceeded smoothly. The research was developed based on interaction between the university and industry researchers; a large part of the PhD student's time was spent at the firm. The project led to the creation of working prototypes of software control systems, some of which were adopted by the industry partner. The knowledge generated by the project was protected by six patents, which were owned by the industry partner. This is a clear case of industry-driven innovation. The industrial partner has a technical problem; the university partner with the appropriate experience (perceived through previous contacts) is approached to provide a workable solution. For the university partner, resolution of this technical problem for the firm did not provide particular tensions or distractions from ongoing research (the PhD project was completed on time). The knowledge generated by the project was geared to solving a specific industry problem and the results were appropriated by the industry partner, who then applied the patent protection in a "traditional" way. The industry partner controlled all dissemination of the knowledge (e.g. all publications related to the project were checked carefully by the firm's IPR department; findings were published with minor delays). The university partner was not frustrated by this level of checking and the slight delays because of experience of interacting with firms for research (supervisor) and strong interest in interacting with the business world (PhD student).

University-driven collaborative project. The innovation is inorganic crystalline phosphors for labelling macromolecules in biological systems. It represents a major improvement over other labelling methods such as radioactive labelling techniques. The potential application of this technology is medical diagnostics. The project originated with the university. The idea was the result of PhD research conducted in the Molecular Cellular Biology Department in the Medical Centre of a large Dutch university. As soon as the potential of the innovation became clear, the university department applied for a patent on the research results. This was not a "ready-to-use" innovation and major development work was required for the technology to be applied within a diagnostic tool. After the patent was granted, research continued funded by NWO grants. It is likely that the patent played a role in the award of this funding to the department. At the same time, the department began to look for potential industrial partners that might be interested in developing the technology. After careful scanning, a suitable industrial partner was identified. It was a US company already engaged in work on the use of crystalline phosphors unknowingly using technology that likely infringed the university patent. A cooperation agreement was drafted and the US company bought the patent rights. This is an example of the co-existence of traditional and heterodox patenting motives. The original patent was used by the university partner to signal-specific

research competencies and reputation. During the collaboration project, the patent rights were transferred to the industry partner that used them for traditional protection and commercializing of the innovation. In this second phase, as the invention was improved and developed by the university and the firm together, the industry partner applied for additional patents. Curiously, after a somewhat tortuous history and due to difficulties related to making the technology viable for practical application and to identifying the market for the technology, the original patent reverted to the university department (the original cooperation contract included a clause about “abandonment” of the patent), a year before it expired, since the firm had decided not to commercialize.⁹ The university continued to work on this project and was awarded a research grant from a US sponsor.

Publicly driven collaborative project. The innovation is a flywheel for application in automobiles to support propulsion of the engine when rapid acceleration is needed. This device, which can be retro-fitted, has the potential to economize on fuel. The innovation was the outcome of a collaborative project involving the Department of Mechanical Engineering in a Dutch technical university and a Dutch manufacturer of transmission systems for automobiles. The partnership was supported by a government programme to support environmentally friendly research projects—especially through university–industry partnerships. The project involved several PhD researchers whose assigned task was to deliver a “proof-of-concept” of a flywheel system. The project led to four patent applications. One of the outcomes of the project was the creation of a spin-off company, since the original company was not interested in diversifying and exploiting the innovation. A university spin-off, owned jointly by the firm and the researchers, was seen as the best way to commercialize the invention. Accordingly, patent rights were transferred to the spin-off company. The technology in question was not immediately applicable, but was developed beyond the embryonic stage. In this case there was a combination of traditional (secure market returns) and heterodox motivations (attract sponsoring and venture capital) for academic patenting.

6. Conclusions

This paper proposed an exploratory framework to examine the motives for academic patenting in different types of university–industry collaborative research projects. Consistent with the previous literature, we proposed three typologies related to the differences in types of innovation, organizational format of research projects and motivations for patenting. *Industry-driven collaborative* projects lead to patenting mainly for traditional-market related motives; *university driven* collaborative projects involve several heterodox motives related to the need for researchers to find industrial partners for future knowledge development, to increase access to public R&D funding, or to support spin-off creation and growth (venture capital and public support). *Publicly driven* projects, aligned to the research agendas of public sponsors, result in patenting for a combination of traditional and heterodox motives. This three-domain space reflects the different links between

⁹ In most of our cases, IPR agreements were not formally established before the collaborative project involving the university and the firm was initiated. IPR agreements applied mainly to projects in Biology. Projects funded by national research sponsors have to abide by the IPR rules set by the research sponsor.

patenting motivations and types of innovation, and the role of industrial partners in proposing, financing and performing specific research projects. Our in-depth evidence on 16 cases of innovations developed or co-developed in Dutch universities supports this taxonomy.

Our evidence suggests that traditional motives for patenting apply to almost all patents, and that heterodox and traditional patenting motivations are not mutually exclusive. Heterodox motivations for patenting are more likely in the case of innovations that are “embryonic”/proof of concept or are radical substitutes for existing technologies. They are also more frequent if research is public financed, and performed mostly by the university leading to a university patent application. Our results suggest also that university researchers, with experience of industry collaboration or interest in future interactions with industry partners, are likely to reproduce traditional market-related motives for patenting.

The most important implication for policy-makers and TTO managers is that academic inventors may be motivated to apply for patents for heterodox reasons. These reasons have generally been ignored in the literature on university patenting, which is unfortunate because they have some implications for policy. Heterodox motivations for patenting, including signalling competences, attracting industrial partners and accessing research funds, may be regarded as positive by policy makers, since they are seen as demonstrating the university’s effort to diffuse the results of academic research and to engage in technology transfer. However, it should be remembered that all patents involve a reduction in social welfare via their effect on reducing competition. In some cases, these negative effects are exacerbated by the effect of a patent related to blocking subsequent technological developments (hold up problems). Innovation policy should limit patenting to only what is required to stimulate investment in the inventive activity.

Second, patents, especially university patents, represent only the commercial and codified aspects of innovation and effective knowledge transfer between university and industry, in most cases, requires articulation using more informal interaction, such as informal contacts, open communication, collaboration and consulting, than the simple licensing of a patent (Cohen *et al.*, 2002; Bekkers & Bodas Freitas, 2008).

Third, our evidence suggests that researchers with longer experience and/or interest in interacting with industry firms tend to reproduce the latter’s objectives and motivations. Hence, too much industry involvement in academic research may restrict communication among scientists because of the secrecy rules set by firms and their keenness to commercialize research results and to patent (Slaughter *et al.*, 2002; Welsh *et al.*, 2008). It may also undermine future pay-offs from academic research not only because of the incentive to focus less on basic curiosity-driven research, but also because it inverts the values of traditional academic freedom (Slaughter *et al.*, 2002; Goldfarb, 2008).

Current incentives to patent research results such as those introduced by many European countries emulating US regulations and practices (see Mowery & Sampat, 2005, for an overview of these attempts to emulate the Bayh-Dole Act) may be exacerbating university budget constraints because they favour patenting at an early stage in the research. As some authors point out, patents are becoming a double-edged policy sword and the balance between their positive and negative effects (especially related to hold up problems that delay follow-up innovations) is becoming increasingly difficult to achieve (Bessen & Meurer, 2008).

The evidence in this paper points to the existence of heterodox motivations for academic patenting but does not shed direct light on the relevance of the consequences of heterodox patenting motives. In light of the existing literature and the evidence in this paper, and until we have a more sophisticated understanding of the phenomenon of heterodox motivations for patenting, we would recommend a more cautious approach to academic patenting.

Our study has some limitations that point to avenues for future research. First the analysis uses unique project level data and, necessarily, relies on a small sample of observations. This limits the type of statistical analysis possible, and means our results are exploratory. Further research is needed on larger samples that exploit different methods of enquiry and analysis. In particular, it would be useful to establish the relative importance of our three “ideal” types. Second, we focus on the motivations for academic patenting, under different collaborative arrangements, and in relation to completed projects. Academic patenting of research results with no industry involvement may fall into the university-driven motivation domain (Göktepe-Hulten & Mahagaonkar, 2010). However, university patenting leading to the creation of university spin-offs by academics, with no industry involvement may also be the result of traditional-market-related motivations. Similarly, academic patent applications in relation to collaborative research in projects cancelled before the patent is granted may be due to heterodox motivations. Further research is needed to address academic motivations in different contexts.

Third, we rely on case studies of university–industry collaboration in the Netherlands. Some characteristics of the motivational spaces might be specific to the Dutch institutional environment—its university regulations, academic career procedures, science policies and research council operations. Research is needed to examine whether these findings could be generalized to other countries given cross-country differences in institutional and careers arrangements.

Acknowledgements

This project was awarded a grant from the Netherlands Organisation for Scientific Research (NWO). We would like to thank Michael van der Borgh; Dirk Veerdesteg, Valentina Tartari, Wouter Smid and Rex van Eijk for excellent research assistance. Moreover, we want to thank Joaquin Azagra-Caro, Pablo D’Este, Julien Penin and Xavier Vence for their constructive comments.
